

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

*November 30, 1874.*

### Anniversary Meeting :

Report of Auditors .....	49
List of Fellows deceased, &c. ....	50
————— elected since last Anniversary .....	50
Address of the President .....	50
Presentation of the Medals .....	68
Election of Council and Officers .....	73
Financial Statement.....	75 & 76
Trust Funds .....	77-79
Account of the appropriation of the sum of £1000 annually voted by Parliament to the Royal Society (the Government Grant), to be employed in aiding the advancement of Science .....	80
Report of the Kew Committee .....	81
List of Presents .....	88

No. 157.—*December 10, 1874.*

	Page
On the Development of the Teeth of the Newt, the Frog, Slowworm, and Green Lizards. By Charles S. Tomes, M.A. ....	93
On the Structure and Development of the Teeth of Ophidia. By Charles S. Tomes, M.A. ....	95
On the Effects of Heat on Iodide of Silver. By G. F. Rodwell, F.R.A.S., F.C.S., Science Master in Marlborough College.....	97
On the Coefficient of Expansion of a Paraffine of high boiling-point. By G. F. Rodwell, F.R.A.S., F.C.S., Science Master in Marlborough College	108
Experiments showing the Paramagnetic condition of Arterial Blood, as compared with the Diamagnetic condition of Venous Blood. By Richard C. Shettle, M.D. ....	116
On the Multiplication of Definite Integrals. By W. H. L. Russell, F.R.S.	120

*December 17, 1874.*

On Polishing the Specula of Reflecting Telescopes. By W. Lassell, F.R.S., V.P.R.A.S. ....	121
• Note on the Vertical Distribution of Temperature in the Ocean. By J. Y. Buchanan, Chemist on board H.M.S. 'Challenger' ....	123
Preliminary Note upon the Brain and Skull of <i>Amphioxus lanceolatus</i> . By T. H. Huxley, Sec. R.S.....	127
Letters received from the Naturalists attached to the Transit-of-Venus Expedition at Rodrigues .....	132
List of Presents .....	136
On some Points connected with the Circulation of the Blood, arrived at from a Study of the Sphymograph-Trace. By A. H. Garrod, B.A., Fellow of St. John's College, Cambridge, Prosector to the Zoological Society. (Plate 5.) .....	140

No. 158.—*January 7, 1875.*

Remarks on a New Map of the Solar Spectrum. By J. Norman Lockyer, F.R.S. ....	152
On the Spectrum of Coggia's Comet. By William Huggins, D.C.L., LL.D., F.R.S., For. Sec. R.A.S. (Plate 6.) .....	154
On Acoustic Reversibility. By J. Tyndall, D.C.L., LL.D., F.R.S. ....	159

*January 14, 1875.*

On a Class of Identical Relations in the Theory of Elliptic Functions. By J. W. L. Glaisher, M.A., Fellow of Trinity College, Cambridge.....	166
On some remarkable Changes produced in Iron and Steel by the Action of Hydrogen and Acids. By William H. Johnson, B.Sc. ....	168

*January 21, 1875.*

	Page
On the Origin and Mechanism of Production of the Prismatic (or Columnar) Structure of Basalt. By Robert Mallet, F.R.S. ....	180
On the Anatomy of the Connective Tissues. By G. Thin, M.D. ....	184

*January 28, 1875.*

On the Theory of Ventilation: an attempt to establish a positive basis for the calculation of the amount of Fresh Air required for an Inhabited Air-space. By Surgeon-Major F. de Chaumont, M.D., Assistant Professor of Hygiene, Army Medical School .....	187
On the Atmospheric Lines of the Solar Spectrum, illustrated by a Map drawn on the same Scale as that adopted by Kirchhoff. By J. B. N. Hennessey, F.R.A.S. ....	201
List of Presents .....	203
On the Alleged Expansion in Volume of various Substances in passing by Refrigeration from the state of Liquid Fusion to that of Solidification. By Robert Mallet, F.R.S. &c. ....	209

*No. 159.—February 4, 1875.*

Remarks on Professor Wyville Thomson's Preliminary Notes on the Nature of the Sea-bottom procured by the Soundings of H.M.S. 'Challenger.' By William B. Carpenter, M.D., LL.D., F.R.S. ....	234
Report to the Hydrographer of the Admiralty on the Cruise of H.M.S. 'Challenger' from July to November 1874. By Prof. Wyville Thomson, F.R.S., Director of the Civilian Scientific Staff on Board .....	245

*February 11, 1875.*

On the Structure and Development of <i>Myriothela</i> . By Prof. Allman, F.R.S. ....	250
Some Particulars of the Transit of Venus across the Sun, December 9, 1874, observed on the Himalaya Mountains, Mussoorie, at Mary-Villa Station, Lat. 30° 28' N., Long. 78° 3' E., Height above Sea 6765 feet.—Note No. I. By J. B. N. Hennessey, F.R.A.S. ....	254
Appendix to Note, dated November 1873, on White Lines in the Solar Spectrum. By J. B. N. Hennessey, F.R.A.S. ....	259

*February 18, 1875.*

On the Number of Figures in the Reciprocal of each Prime Number between 30,000 and 40,000. By William Shanks .....	260
On the Nature and Physiological Action of the <i>Crotalus</i> -poison as compared with that of <i>Naja tripudians</i> and other Indian Venomous Snakes; also Investigations into the Nature of the Influence of <i>Naja</i> - and <i>Crotalus</i> -poison on Ciliary and Amœboid Action and on <i>Vallisneria</i> , and on the Influence of Inspiration of Pure Oxygen on Poisoned Animals. By T. Lauder Brunton, M.D., F.R.S., Sc.D., M.R.C.P., and J. Fayrer, C.S.I., M.D., F.R.C.P. Lond., F.R.S.E., President of the Medical Board at the India Office .....	261

*February 25, 1875.*

	Page
Communication from Mr. Robert Mallet, F.R.S., on the large Mercator Chart of the World .....	278
On the Integration of Algebraical Functions, with Illustrations in Mechanics. By W. H. L. Russell, F.R.S. ....	279
The Bakerian Lecture.—On the Forms of Equipotential Curves and Surfaces and Lines of Electric Force. By Prof. W. G. Adams, M.A., F.R.S. ..	280
List of Presents .....	285
On the Physiological Action of the Chinoline and Pyridine Bases. By John G. M'Kendrick and James Dewar, Edinburgh.....	290

*No. 160.—March 4, 1875.*

On the Tides of the Arctic Seas.—Part VI. Tides of Port Kennedy, in Bellot Strait, in July 1859. By the Rev. Samuel Haughton, M.D. Dublin, D.C.L. Oxon., F.R.S., Fellow of Trinity College, Dublin.....	299
Note on the Value of a certain Definite Integral. By L. Todhunter, M.A., F.R.S., Honorary Fellow of St. John's College, Cambridge.....	300
On the Determination, at Sea, of the Specific Gravity of Sea-water. By J. Y. Buchanan, Chemist on board H.M.S. 'Challenger' .....	301

*March 11, 1875.*

On Traumatic Inflammation of Connective Tissue. By G. Thin, M.D. ..	309
Report on Observations of the Transit of Venus made at Luxor, Upper Egypt, 9th December, 1874. By Vice-Admiral E. Ommanney, C.B., F.R.S. ....	314
Preliminary Abstract of Approximate Mean Results with the Invariable Pendulums Nos. 4 and 1821, in continuation of the Abstract published in vol. xix. of the Proceedings. By Captain W. J. Heaviside, R.E.....	316

*March 18, 1875.*

On the Behaviour of the Hearts of Mollusks under the influence of Electric Currents. By Dr. M. Foster, F.R.S., and A. G. Dew-Smith, B.A., of Trinity College, Cambridge .....	318
On the Absorption-Spectra of Metals volatilized by the Oxyhydrogen Flame. By J. Norman Lockyer, F.R.S., and W. Chandler Roberts, Chemist of the Mint .....	344
On the Liqutation, Fusibility, and Density of certain Alloys of Silver and Copper. By W. Chandler Roberts, Chemist of the Mint .....	349

PROCEEDINGS  
OF  
THE ROYAL SOCIETY.

---

*November 19, 1874.*

WILLIAM SPOTTISWOODE, M.A., Treasurer and Vice-  
President, in the Chair.

In pursuance of the Statutes, notice of the ensuing Anniversary Meeting was given from the Chair.

General Boileau, Mr. De La Rue, Capt. Evans, Dr. Gladstone, and the Right Hon. Lyon Playfair, having been nominated by the President, were elected by ballot Auditors of the Treasurer's Accounts on the part of the Society.

The decease of Mrs. Hooker having been mentioned from the Chair, Sir James Alderson proposed, and General Boileau seconded, the following Resolution, which was unanimously agreed to:—"That the Royal Society desire to condole with their President for his loss, and to express to him their deep sympathy in his great affliction."

Dr. Henry Wyldbore Rumsey was admitted into the Society.

The Presents received were laid on the table, and thanks ordered for them.

The following Papers were read:—

- I. "Note to the 'Report on the Exploration of Brixham Cave' (Phil. Trans. 1873)." By G. BUSK, F.R.S., V.P.L.S. Received June 22, 1874.

With reference to Prof. Owen's correction of the erroneous English equivalent for *Lagomys spelæus* (which occurs, not in the Report on the Animal Remains, but in the "General Conclusions respecting the Brixham Cave," accompanied, however, with the proper scientific name), I have merely to remark that it is of course a very obvious erratum. It is one,

...this well-known fact is hardly, in the  
a claim to "original discovery."

On the Tides of the Arctic Seas.—Part IV.  
Northumberland Sound at the Northern Outlet  
Channel.—Part V. The Tides of Refuge Cove  
Channel." By the Rev. SAMUEL HAUGHTON, M.  
A.C.L. Oxon. Received July 11, 1874.

(Abstract.)

...tidal observations were made by Sir Edward  
on board of H.M.S. 'Assistance,' in the summer of  
...resting, from the fact that they were made in the  
...which tidal observations have been ever recorded.  
...a discussion of the heights and times of high and low  
...; partial results have been obtained, which, it is  
...extended and corrected, by taking into account the  
other phases of the tides.

## III. "On Musical Duodenes, or the Theory of Constructing Instruments with Fixed Tones in Just or Practically Just Intonation." By ALEXANDER J. ELLIS, F.R.S., F.S.A., F.C.P.S., F.C.P. Received October 28, 1874.

This paper is intended to complete and supplement three papers on Music which I have already read before the Royal Society<sup>1</sup>. It contains a more complete theory of temperament, embracing that indicated by Helmholtz<sup>2</sup>, but not worked out by him, and its application to the theory of constructing musical instruments with an intonation practically just, without change of fingering, and, if there are three or four performers, without change of mechanism. The name *Duodene* refers to that collection of *twelve* notes, suitable to the present manuals, which is made the unit of construction. To obtain its precise form, and determine the number and value of all such duodenes as it is necessary to tune, I have been obliged to indicate a theory of harmonic scales and modulation, which I believe to be entirely new, and which has of course other uses. The great extent of the subject obliges me to confine this part of my paper to a mere indication.

A. *Notation of Pitch.*

The letters C, D, E, F, G, A, B indicate both musical tones and the number of vibrations made by the prime or lowest partial tone of each in a second; so that, C being known,

$$D = \frac{9}{8} C, E = \frac{5}{4} C, F = \frac{4}{3} C, G = \frac{3}{2} C, A = \frac{5}{3} C, B = \frac{15}{8} C.$$

The marks ♯ ♮ † ‡ ¶ ♭ are used for fractional multipliers, having the following names and values:—

sharp, ♯	= $\frac{135}{128}$	flat, ♭	= $\frac{128}{135}$
high, †	= $\frac{81}{80}$	low, ‡	= $\frac{80}{81}$
ekhismic, ¶	= $\frac{32805}{32768}$	hyposkhismic, ♭	= $\frac{32768}{32805}$

<sup>1</sup> "On the Conditions, Extent, and Realization of a Perfect Musical Scale on Instruments with Fixed Tones," read Jan. 21, 1864, printed at length in *Proceedings*, vol. xiii. p. 93; "On the Physical Constitution and Relations of Musical Chords," and, lastly, "On the Temperament of Musical Instruments with Fixed Tones," both read on June 16, 1864, and printed at length in the *Proceedings*, vol. xiii. p. 392 and p. 404.

<sup>2</sup> *Tonempfindungen*, 3rd ed. p. 495.

Another object, therefore, is to make that dissonance as little annoying as possible.

We find immediately by actual multiplication,

$$\left(\frac{3}{2}\right)^{12} \cdot \left(\frac{1}{2}\right)^7 = \frac{531441}{524288} = \sharp\flat, \text{ the comma of Pythagoras,} \dots \dots \dots (1)$$

$$\left(\frac{4}{5}\right)^3 \cdot 2 = \frac{128}{125} = \sharp\sharp, \text{ the diesis} \dots \dots \dots (2)$$

Multiplying these equations together, and extracting the cube root,

$$\left(\frac{3}{2}\right)^4 \cdot \frac{4}{5} \cdot \left(\frac{1}{2}\right)^2 = \frac{81}{80} = \sharp, \text{ the comma (of Didymus)} \dots \dots \dots (3)$$

Dividing (1) by (3),

$$\left(\frac{3}{2}\right)^8 \cdot \frac{5}{4} \cdot \left(\frac{1}{2}\right)^6 = \frac{32805}{32768} = \flat, \text{ the skhisma.} \dots \dots \dots (4)$$

On these equations depend all *uniform* temperaments in which every Fifth and major Third preserves the same ratio throughout.

Let  $V, T, k, s$  be any four fractions having relations similar to  $\frac{3}{2}, \frac{4}{5}, \sharp$  and  $\flat$  respectively in (1) and (2); then

$$V^{12} \div 2^7 = ks, \text{ and } 2 \div T^3 = k^2 \div s \dots \dots \dots (5, 6)$$

Subtracting the logarithms of (1) and (2) from the logarithms of (5) and (6) respectively, we find

$$\log V = \log \frac{3}{2} - \frac{1}{12} \cdot (\log \sharp - \log k + \log \flat - \log s), \dots \dots \dots (7)$$

$$\log T = \log \frac{5}{4} + \frac{2}{3} \cdot (\log \sharp - \log k) - \frac{1}{3} (\log \flat - \log s), \dots \dots \dots (8)$$

which are the fundamental equations of all temperament, and are identities, of course, for just intonation. As they contain 4 unknown expressions, two may be assumed and the rest found, giving rise to an endless variety of temperaments. Without discussing these generally, the following cases should be mentioned:—

*Commatic System* (for which  $k=1$ ).—This is the only system discussed in my previous paper, where 50 cases were considered.

1. *Quintal* or Pythagorean Temperament. Assume  $k=1$ , and  $V=\frac{3}{2}$ , then by (7),

$$\log \sharp + \log \flat = \log s;$$

whence by (8),

$$\log T = \log \frac{5}{4} + \log \sharp.$$

This temperament proves to be thoroughly unsuitable for harmony.

2. *Tertian, Mesotonic* or Mean Temperament. Assume  $k=1$  and  $T=\frac{5}{4}$ , then by (8),

$$2 \log \sharp = \log \flat - \log s;$$

$$\log V = \log \frac{3}{2} - \frac{1}{12} \cdot (\log t + \log \mathbb{N}),$$

$$\log T = \log \frac{5}{4} + \frac{1}{3} \cdot (2 \log t - \log \mathbb{N}).$$

$\log t = 0.005\ 3950\ 319$  (whence  $\frac{1}{11} \log t = 0.000\ 4901\ 071$ , we may, for all acoustical purposes, neglect  $\frac{1}{11} \log t$ , and hence that

$$\log V = \log \frac{3}{2} - \frac{1}{11} \cdot \log t = \log \frac{3}{2} - \log \mathbb{N},$$

$$\log T = \log \frac{5}{4} + \frac{7}{11} \cdot \log t = \log \frac{5}{4} + 7 \log \mathbb{N}.$$

is the only uniform temperament which requires no commas, and hence, although very ill suited to harmony, has been generally adopted by almost all musicians.

*Pythagorean System* (for which  $s=1$ ).

*Pythagorean* or Arabic, according to Helmholtz's indication.

Assume  $s=1$  and  $V=\frac{3}{2}$ ; then by (7),

$$\log k = \log t + \log \mathbb{N},$$

,

$$\log T = \log \frac{5}{4} - \log \mathbb{N}.$$

Pythagoreans tune 17 tones to form 16 perfect Pythagorean intervals, which are

my name for  $\sqrt[8]{\sharp}$ . Since  $\log \dagger = 88 \log \sigma$  very nearly, one comma may be said to contain 88 skhists. Skhistic temperament is indistinguishable from just intonation, and I shall use it in the theory of constructing instruments. If in Table I. we suppose the horizontal intervals to be still  $\frac{5}{4}$ , but the vertical intervals to be  $\frac{3}{2\sigma}$ , and the sign  $\dagger$  to stand for  $\frac{81}{80} \sqrt[8]{\flat}$ , while  $\dagger\dagger = 1$  as before, then this Table represents skhistic relations; so that if from any note, as  $E\flat$  (col. 5, line  $x$ ), we proceed by 8 skhistic Fifths up to  $\dagger B$  and then one major Third to the right, we find a tone  $D\sharp$ , which, when reduced to the same Octave, is identical with  $E\flat$ . We thus find a number of *skhistic synonyms* shown in Tables II. & III.

We may express the *errors in the temperaments* just discussed in terms of skhists thus, using  $\sharp 56\sigma$  to mean "too sharp by 56 skhists," and so on, and 0 to mean "no error":—

Just.	1. Quintal.	2. Tertian.	3. Equal.	4. Skhismic.	5. Skhistic.
Minor Third . . . .	$\flat 88\sigma$	$\flat 22\sigma$	$\flat 64\sigma$	$\sharp 8\sigma$	$\flat 1\sigma$
Major Third . . . .	$\sharp 88\sigma$	0	$\sharp 56\sigma$	$\flat 8\sigma$	0
Fourth . . . . .	0	$\sharp 22\sigma$	$\sharp 8\sigma$	0	$\sharp 1\sigma$
Fifth . . . . .	0	$\flat 22\sigma$	$\flat 8\sigma$	0	$\flat 1\sigma$
Minor Sixth . . . .	$\flat 88\sigma$	0	$\flat 56\sigma$	$\sharp 8\sigma$	0
Major Sixth . . . .	$\sharp 88\sigma$	$\sharp 22\sigma$	$\sharp 64\sigma$	$\flat 8\sigma$	$\sharp 1\sigma$

The error of one skhist is quite inappreciable by the most practised ears in melody, and can be detected harmonically only by very slow beats for tones in the highest Octaves used in music.

6. *Cyclic Temperaments.* The following method is far more general than that given in my previous paper (Proc. vol. xiii. p. 412). Put

$$\begin{aligned} m \cdot \log V &= v \cdot \log 2, & m \cdot \log k &= q \cdot \log 2, \\ m \cdot \log T &= t \cdot \log 2, & m \cdot \log s &= z \cdot \log 2, \end{aligned}$$

and, after substituting these values for  $\log V$ ,  $\log T$ ,  $\log k$ ,  $\log s$  in the logarithms of equations (5) and (6), divide out by  $\log 2$ , and multiply up by  $m$ . Then

$$12v - 7m = q + z, \quad m - 3t = 2q - z \dots\dots\dots (9, 10)$$

Take any integral values for  $q$  and  $z$ , and find the integral values which satisfy one of these indeterminate equations for  $v$ ,  $m$ , or  $t$ ,  $m$ , and substitute in the other, taking the resulting integral values of  $t$  or  $v$  respectively. The five integral values determine a *cycle* in which the Octave is divided into  $m$  aliquot parts, which may be termed *octs*,  $v$  of which make a Fifth,  $t$  a major Third,  $q$  a comma, and  $z$  a skhisma of "the cycle of  $m$ ." Most of the results are valueless, but the following present either theoretical convenience or historical interest:—

No.	Cycle of <i>m.</i>	Fifth, <i>v.</i>	Major Third, <i>t.</i>	Comma, <i>q.</i>	Skhisma, <i>s.</i>
1	30103	17609	9691	539	48
2	3010	1761	969	55	7
3	301	176	97	5	0
4	53	31	17	1	0
5	53	31	18	0	1
6	31	18	10	0	-1
7	12	7	4	0	0

Of these, the first three are here, I believe, for the first time shown to be true cyclic temperaments.

1. The cycle of 30103 is such an excellent representative of just intonation (giving even 6 octs for the skhist), that it can be used without sensible error, in place of ordinary logarithms, to reduce the relations of intervals to addition and subtraction, for general use among musicians or learners unacquainted with higher arithmetic. By dividing out by 100,000 we obtain almost precisely the five-figure logarithms of the intervals.

2. The cycle of 3010 is almost as correct, with smaller numbers.

3. The cycle of 301 is almost a perfect representation of skhistic temperament, in which the skhisma is eliminated, and for that reason becomes perhaps the most practical representation of general musical intonation.

4. The first cycle of 53 is Nicholas Mercator's representation of just intonation, but it is more correctly a representation of skhistic temperament, and not so good as No. 3<sup>1</sup>.

5. The second cycle of 53 is a very accurate representation of Pythagorean intonation, and has actually been proposed for the violin by Drobisch.

6. The cycle of 31 is Huyghens's *Cyclus Harmonicus*, and closely represents the tertian or mean temperament.

7. The cycle of 12 is the ordinary equal temperament, and its principal convenience consists in the very small number of its octs, here called Semitones.

*Unequal Temperaments*, whether they consist of 12 selected tones from uniform temperaments, or of 12 tones turned intentionally false (see my former paper, *Proc.* vol. xiii. pp. 414-417, for their theory), are now abandoned. But the difficulty of tuning equal temperament by estimation of ear, or even by the monochord, and of retaining the intonation of the piano or organ unchanged for even an hour, makes all temperaments in actual use really unequal. The difficulty of original tuning by estimation

<sup>1</sup> When this paper was read, I mentioned that this was the cycle used by Mr. Bosanquet in his paper read before the Royal Society on 30th January, 1873.

of ear in the case of skhistic temperament, where the Fifths have to be flattened by an almost inaudible skhist, is so much enhanced as to be insuperable except by Scheibler's method<sup>1</sup>. Hence it is necessary to find a practical substitute. This I term

*Unequally Just Intonation*.—Suppose that the 48 tones marked off by a dotted line in Table I. have to be tuned in this substitute for skhistic intonation. Tune C to the fork. Take 4 just Fifths up (or Fourths down), C to G, G to D, D to †A, †A to †E, without beats; and three just Fifths down (or Fourths up), C to F, F to B♭, B♭ to E♭. Then tune C to E as a just major Third up, without beats, and from E proceed to its just Fifth B, verifying the result by determining that it is a just major Third above G, and so on to G♯ up and †G down. Then if from G♯ we proceeded to the just Fifth, D♯, the resulting tone would be exactly one skhisma sharper than E♭, whereas in skhistic intonation it would be identical with E♭, as already shown. It is needless to say that no tuner could effect this exact difference of a skhisma, but he will come practically near it, and the error is that of the Fifth (the least of the errors) in equal temperament. If we were to proceed in this way for all the six columns of 8 tones marked off in Table I., we should have just major Thirds throughout, and just Fifths also in all but 5 cases—namely, †D♯♯ to †B, B♯ to †G, G♯ to E♭, †E to C♭, and †C to †A♭♭, each of which would be too flat by one skhisma. Since †G (Table I. col. 6, line *x*) is a just major Third below †B, and a just minor Third above †E, but †E is a whole skhisma flatter than †D♯♯ (col. 8, line *p*), which would be played for †E, it follows that the minor Third, †D♯♯ to †G, would be a skhisma too flat or close; and similarly that the minor Thirds, B♯ to E♭, G♯ to C♭, and †E to †A♭♭, or 4 minor Thirds on the whole, would be a skhisma too flat<sup>2</sup>. Hence this style of tuning gives 5 Fifths and 4 minor Thirds, as

<sup>1</sup> Calculate the logarithms of the ratios of all the skhistic tones by perpetual addition or subtraction of 0.1760300 ( $=\log \frac{3}{2} - \log \sigma$ ) to or from 0, continually adding or subtracting 0.3010300 ( $=\log 2$ ) to make the results positive and lie between this and 0. Add the logarithm of the vibrational number of C, and then find the numbers (to three places of decimals) corresponding to these logarithms. This gives the vibrational numbers of all the skhistic tones in the Octave, of which 48 will be required. Subtract 4 from each of these values, and procure tuning-forks giving exactly the tones thus determined to at least the hundredth of a vibration in a second. These may be obtained of the great manufacturer of acoustic apparatus, Mons. R. Koenig, of Paris; but it is necessary to state that the English and German (not the French) system of counting vibrations is to be used. Then tune each tone roughly to the corresponding fork, and afterwards *sharpen* it until it beats 4 times in a second with the fork. By this means, and by this means only, with great care and attention, the pitch may probably be obtained with sufficient accuracy to distinguish skhistic from just intonation. And similarly for equal and tertian intonation.

<sup>2</sup> Taking the cycle of 30103, †G contains 17070, †B 26761, and †D♯♯ 9200 octs. Hence the Fifth, †D♯♯ to †B, has only 17561 in place of 17609 octs, and the minor Third, †D♯♯ to †G, only 7870, in place of 7918 octs—that is, in each case 48 octs too little; that is, these intervals are one skhisma too flat.

bad as the best intervals (Fifths) in equal temperament, and all the other intervals absolutely just. Hence the name *unequally just*. In future I shall consider that skhistic intonation is practically realized by unequally just intonation, for which the practical rule is:—*tune six tones making just major Thirds without beats* (as  $\sharp F\flat$  to  $\sharp A\flat$  to C to E to  $\sharp G\sharp$  to  $\sharp B\sharp$ , line 1 in Table I.), and from each of them *tune seven other tones making just Fifths* (as C to G to D to  $\sharp A$  to  $\sharp E$ , and C to F to  $B\flat$  to  $E\flat$ , in col. 5 of Table I.).

*Saunders's "Tilting Action."*—Before proceeding to show that 48 skhistic tones suffice for modern modulational music, it will be useful for future constructions to remark that a method of realizing all the effects which I contemplated by my duplex finger-board (Proc. vol. xiii. p. 422) has been invented by Mr. T. W. Saunders<sup>1</sup>, by means of stops, which allow the manual and fingering to remain unaltered. Two sets of harmonium vibrators are arranged one behind the other, tuned in tertian intonation (by means of beats, counted by a pendulum, which gives a fairly accurate means of approximating to the correct result) as follows, the capital letters referring to the white or long digitals, and the small letters to the black or short digitals, a mode of distinction which I shall constantly employ:—

Back . . . . .	$B\sharp$	$d\flat$	$C\sharp\sharp$	$e\flat$	$F\flat$	$E\sharp$	$g\flat$	$F\sharp\sharp$	$a\flat$	$G\sharp\sharp$	$b\flat$	$C\flat$
Front . . . . .	C	$c\sharp$	D	$d\sharp$	E	F	$f\sharp$	G	$g\sharp$	A	$a\sharp$	B

There are 12 stops<sup>2</sup>, one corresponding to each digital in the Octave, which, by a "tilting action," enables one, and one only, out of the two vibrators in the same column, as shown above, to be "damped" at pleasure throughout all the Octaves of the instrument. When all the stops are pushed in, the front vibrators only are free, and any one may be exchanged for a back vibrator by pulling out its stop. Hence 24 out of 27 tones are under the command of the player;  $B\flat\flat$ ,  $E\flat\flat$ ,  $A\flat\flat$  are omitted.

### C. Harmonic Scales.

A series of tones, each of which is consonant with two other tones in the same series that are themselves consonant with each other, forms what I here mean by an *harmonic scale*. This was not the principle on which scales were originally formed; but this is the way in which the pitch of the tones must be determined for the just intonation of modern harmony and modulation.

<sup>1</sup> As Mr. Saunders has not patented his invention, I am unable to give more than the indications in the text, and refer to him personally, at E. Laohenal's Concertina Manufactory, 4 Little James Street, Bedford Row, W.C. His invention offers great facilities for the construction of experimental instruments in any uniform or just intonation. His harmonium was shown when this paper was read.

<sup>2</sup> In the specimen shown there are only 9 stops, the  $C\sharp\sharp$ ,  $F\sharp\sharp$ ,  $G\sharp\sharp$  having been omitted; but as the principle admits of the construction of 12 stops as easily as 9, the complete form is mentioned in the text.

*The Harmonic Elements* are the Fifth,  $C \times G \left( = \frac{3}{2} \right)$ , the major Third,  $C + E \left( = \frac{5}{4} \right)$ , and the minor Third,  $C - \sharp E \flat \left( = \frac{6}{5} \right)$ , using a notation which I have found practically very convenient for representing the intervals between two tones; the symbols  $\times$ ,  $+$ ,  $-$  are not to be employed with any other meaning between the names of tones. In these elements it is supposed that either note may be raised or depressed by any number of Octaves, or be accompanied by such Octaves of itself.

*The Harmonic Cell, or Unit of Concord*, consists of a major triad,  $C + E - G$ , and a minor triad,  $C - \sharp E \flat + G$ , arranged as in the margin, and having the same First  $C$ , and hence the same Fifth  $G$ . The Fifth  $C \times G$  is placed vertically, the two major thirds,  $C + E$  and  $\sharp E \flat + G$ , are horizontal, and the two minor Thirds,  $C - \sharp E \flat$  and  $E - G$ , slope obliquely from the bottom upwards to the left. These positions, then, replace the symbols  $\times$ ,  $+$ ,  $-$ . Allowing any one of the tones to be altered by any number of Octaves, or to have Octaves of itself added, and any tone to be taken as the First, this *cell*, whence all harmony is *developed*, contains every chord recognized by musicians as a concord in Tertian Harmony—that is, harmony depending on Octaves, Fifths, and Thirds alone, excluding natural Sevenths  $\left( = \frac{7}{4} \right)$ , which form Septimal Harmony. By Table I. cells can be readily constructed on any tone as a First.

*The Harmonic Heptad, or Unit of Chord-relationship*, consists of two cells, the First of one being the Fifth of the other, as in the margin. Allowing Octave variations as before, this contains all the three major and three minor triads which have  $C$  as one of their constituents, and are thus related in the first degree. Two of these chords, the minor triad  $A - C + E$  on the right or major side, and the major triad  $\sharp A \flat + C - \sharp E \flat$  on the left or minor side, connecting the two cells and due to their union, may be called *union triads*, to distinguish them from the four *cell triads*. The heptad also contains all *con-dissonant triads* (as I term them), consisting of three tones, two of which are consonant with  $C$  but dissonant with each other. Of these the *trine*  $\sharp A \flat + C + E$ , which forms the central horizontal line, is most important for future work.

*The Harmonic Decad, or Unit of Harmony*, consists of two heptads having a common cell, and hence of three cells, the Fifth of the first, lowest, or *subdominant* cell, and the Fifth of the second, middle, or *tonic* cell, being the First of the second cell, and First of the third, highest, or *dominant* cell, respectively. The decad contains three major and three minor cell triads, and two major and two minor union triads—that is, ten triads in all, together with all the discords possible without

modulation. The First of the tonic cell is called the *tonic of the decad*, and gives its name to it. The example, therefore, is a C decad.

*Harmonic Trichordals* consist of three triads, one from each cell in a decad, and form eight groups. Contracting major triad and minor triad into *ma* and *mi* respectively (with Italian vowels), and naming the three-cell triads in order from bottom to top, these 8 trichordals are distinguished as follows in the C decad. The triads are spread out and marked by + and -, and the terminal triads are repeated in part with an interposed | to indicate the dissonant interval of a Pythagorean minor Third =  $\frac{80}{81} \cdot \frac{6}{5} = \frac{32}{27}$ , so that all the harmonies, consonant and dissonant, peculiar to any trichordal, may be collected at a glance.

i. <i>Mamama</i> .....	B - D   F+ A - C+ E - G+ B - D   F+ A
ii. <i>Mimema</i> .....	B - D   F-†Ab+C+ E - G+ B - D   F-†Ab
iii. <i>Mamima</i> .....	B - D   F+ A - C-†Eb+G+ B - D   F+ A
iv. <i>Minima</i> .....	B - D   F-†Ab+C-†Eb+G+ B - D   F-†Ab
v. <i>Mamami</i> .....	†Bb+D   F+ A - C+ E - G-†Bb+D   F+ A
vi. <i>Minami</i> .....	†Bb+D   F-†Ab+C+ E - G-†Bb+D   F-†Ab
vii. <i>Mamimi</i> .....	†Bb+D   F+ A - C-†Eb+G-†Bb+D   F+ A
viii. <i>Minimi</i> .....	†Bb+D   F-†Ab+C-†Eb+G-†Bb+D   F-†Ab

Each of these 8 trichordals contains 7 tones, and when these are reduced to one Octave and sounded in order of pitch, they form that particular scale in which a piece of music is usually written. But in repeating them each may begin on any tone of the seven, giving 7 *modes* (in the ancient Greek sense) to each trichordal. To distinguish these, change the *m* of the name of the triad containing the initial tone into *p* when it is its First (*p*rima), *t* when it is its Third (*t*ertia), and *qu* when it is its Fifth (*qu*inta), which last is of course required for the highest or dominant triad only. The final cadence fully distinguishes the 56 resulting *harmonic scales*. Of these I append such as are usually acknowledged, making them all begin with C, and changing the decad accordingly. Between the tones I use (.) for the Semitone  $\frac{16}{15}$ , (:) for the high Semitone  $\frac{27}{26}$ , (..) for the minor Tone  $\frac{10}{9}$ , (...) for the major Tone  $\frac{9}{8}$ , and (·) for the augmented tone  $\frac{75}{64}$ .

1. C *mapáma*, or ordinary scale of C major.

c ... d .. e . f ... g .. a ... b . c'.

2. F *mamapá*, one of Helmholtz's modes of the Fourth, or *Quartengeschlecht*.

c .. †d ... e . f ... g .. a . b♭ ... c'.

3. C *mipáma*, Helmholtz's minor-major mode, or *Moll-Durgeschlecht*.

c ... d .. e . f ... g . †a♭ ∴ b . c'.

4. C *mapíma*, Helmholtz's mode of the minor Seventh with the leading note, or *Septimengeschlecht mit dem Leitton*, a very usual form of the modern ascending scale of C minor.

$$c \dots d . \sharp e \dots f \dots g \dots a \dots b . c'.$$

5. C *mipíma*, the theoretical modern ascending scale of C minor.

$$c \dots d . \sharp e \dots f \dots g . \sharp a \dots b . c'.$$

6. F *mamapí*, considered by Helmholtz (*op. cit.* p. 434. no. 6) as a variant of the mode of the minor Seventh.

$$c \dots \sharp d : \sharp e \dots f \dots g \dots a . b \dots c'.$$

7. C *mapími*, Helmholtz's mode of the minor Seventh without the leading note.

$$c \dots d . \sharp e \dots f \dots g \dots a : \sharp b \dots c'.$$

8. C *mipími*, Helmholtz's mode of the minor Third, or *Terzengeschlecht*, the ordinary form of the modern descending scale of C minor.

$$c \dots d . \sharp e \dots f \dots g . \sharp a \dots \sharp b \dots c'.$$

9. F *mimipí*, Helmholtz's mode of the minor Sixth, or *Sextengeschlecht*.

$$c . \sharp d \dots \sharp e \dots f \dots g . \sharp a \dots b \dots c'.$$

These 56 harmonic scales are all that can be produced without modulation.

To retain old names as much as possible, C *mapíma* will be called C *major*, and all three, C *mipími*, *mipíma*, *mapíma*, will be considered as making up C *minor*, whilst other forms will be termed *unusual minor scales*. All these, however, and more of the 56 scales mentioned above, actually occur in modern music, at least for short phrases, although the usual *major* and *minor* alone characterize whole compositions.

#### D. Modulation and Duodenation.

Although a decad consists of complete triads and cells, yet it is evident that one or two of the cells may be made parts of other decads, and that the *union* triads may be regarded as parts of cells left incomplete. The tones forming these cells and unions are therefore *ambiguous*, and there is always a tendency to complete them in a different way from that in the original decad, or, in other words, to proceed to the other decads of which they form a part. By an extension of the term modulation, which originally referred to a mere change of mode, this change of decad might still be called *modulation*, although *decadation* might be more appropriate.

... as a heptad as tonics, and contains 24  
 the heptadecad of C, in which the decad of C is p  
 the added tones necessary to complete the hepta  
 on the right *solfeggio* names are proposed as substit  
 ith Italian vowels. These names are founded o  
 onic Solfaists, and are suitable to *any* original ton  
 introduced because singers in just intonation should  
 the “mental effect” of each of these tones in relati  
 he decads are named from the names of the tones i  
 he G decad is the dominant or *So* decad; the F the  
 cad; the A the right relative, or major Sixth, or *L*  
 e left relative or minor Third or *Mo* decad; the  
 ative or major Third, or *Mi* decad; and the †A♭ is  
 minor Sixth or *Lo* decad—all with reference to th  
 ad. These six decads are related to the original  
 ree. The dominant and subdominant decads hav  
 relative and correlative decads have each six tone  
 original decad. The dominant decad raises two to  
 na,  $\frac{81}{80}$ , to †f and †a, and one, F, by a sharp,  $\frac{135}{128}$ , t  
 nt depresses two tones, †B♭ and D, by a comma,  
 D, by a sharp, to d♭. These two decads are there  
 original. The right relative decad depresses  
 a, to †d, and raises three tones, F, C, G, by  
 c♯, †g♯. The right correlative decad —  
 and three tones —

chordal, with the fullest and best harmonies, is undoubtedly the *mamama* or *major*, consisting of the central and right columns of the decad containing it, modulation (or decadation) to the *right* is more common than modulation to the *left*; and, owing to the closer relationship, modulation to the right relative is more common than into the right correlative, which generally occurs as a *vertical* (dominant) modulation from the latter. Vertical (dominant or subdominant) modulations are, however, the most common of all, unconsciously (owing to commatic temperament) into the subdominant (when the minor chord,  $\sharp d - f + a$ , is used for the chord of the added Sixth,  $f + a \mid d$ ), and consciously into the dominant (in which, however, only  $f\sharp$ , and not  $\sharp a$ , is commonly recognized).

The vertical modulation is so common that it influences scales, producing actual tetrachordals, which are disguised in melody by being occasionally deprived of their extreme tones, so as to reduce their apparent number at any time to 7. The fourth chord may be added on to the name by a hyphen. Thus we have

C *ma-mapáma* . . . . .  $b\flat + \sharp d - f + a - c + e - g + b - d$ ,

in which the  $b\flat$  is seldom touched except in the chord of the dominant Seventh,  $c + e - g \mid b\flat$ , and then not in melody, but  $\sharp d$  often comes into melody. Similarly we have

C *mapáma-ma* . . . . .  $f + a - c + e - g + b - d + f\sharp - \sharp a$ ,

where  $\sharp a$  is not touched in the melody. But in minor scales this is more marked, as

A *mimipá-ma* . . . . .  $\sharp d - f + a - c + e + \sharp g\sharp - b + \sharp d\sharp - f\sharp$ ,

where  $\sharp d$  and  $f\sharp$  are not touched in the melody; so that the scale reads

$e . f \therefore \sharp g\sharp . a \dots b . c \therefore \sharp d'\sharp . e'$ ,

with 4 semitones and 2 augmented tones, which has an extremely strange effect<sup>1</sup>. Another scale of this kind is

A *mimipí-ma* . . . . .  $\sharp d - f + a - c + e - g + b + \sharp d\sharp - f\sharp$ ,

which occurs in the modern treatment of Helmholtz's mode of the minor Sixth (No. 9, above). The apparent scale is

$e . f \dots g \dots a \dots b . c \therefore \sharp d'\sharp . e'$ ,

which has 3 Semitones. These are, in fact, all cases of vertical modulation (or decadation); and it is only by recognizing this fact that we are able to reduce them to just intonation. They have not been, however, hitherto so conceived, and hence it became necessary, for the purposes of

<sup>1</sup> This scale and its harmonies are taken from C. Child Spenser's 'Rudimentary and Practical Treatise on Music,' vol. ii. p. 42. He does not acknowledge either  $\sharp d$  or  $f\sharp$ ; but he really uses  $\sharp d$  in his second chord,  $\sharp d a \sharp d' f'$ , and he only avoids  $f\sharp$  by using  $f + a \dots b + \sharp d\sharp$  for the usual chord of the dominant Seventh,  $b + \sharp d\sharp - f\sharp \mid a$ .

this paper, to explain them. A means of putting the strange-looking chords<sup>1</sup>,  $f+a \dots b+\sharp d\sharp$ , and  $f+a-c$  with  $\sharp d\sharp$ , or  $f+a$  with  $\sharp d\sharp$ , which they contain, under the hands of the performer on justly intoned instruments, is absolutely necessary.

*The Harmonic Duodene or Element of Modulation*, as distinguished from the heptadecad or unit of modulation, contains the 12 tones inclosed within an oblong in the figure of the heptadecad. It is seen to contain a complete decad of C and two additional tones,  $f\sharp$  and  $d\flat$ , which I term *mutators*, as each of them is part of two cells, and hence lead the old decad to *change* into the new decads containing them. Thus  $f\sharp$  is part of

the vertical cell  $\sharp f \quad \sharp a$  and of the lateral cell  $D \quad f\sharp$   
 $D \quad f\sharp$   $B \quad \sharp d\sharp$

and hence leads both to the dominant decad and to the right correlative decad. Again,  $d\flat$  is a part of

the vertical cell  $d\flat \quad F$  and of the lateral cell  $\sharp f\flat \quad \sharp A\flat$   
 $b\flat \quad \sharp d$   $d\flat \quad F$

and hence leads to the subdominant decad and to the left correlative decad. But these mutators,  $f\sharp$  and  $d\flat$ , also complete two scales left incomplete in the decad because they required vertical modulation (or decadation), namely,

$\sharp A\flat$  *mapáma* . . .  $d\flat + f - \sharp a\flat + c - \sharp e\flat + g - \sharp b\flat$ , and  
 $E$  *mipími* . . .  $a - c + e - g + b - d + f\sharp$ ,

and also complete the peculiar chords,  $d\flat + F \dots G + B$ ,  $\sharp A\flat + C \dots D + f\sharp$ ,  $D\flat + F - \sharp A\flat$  with  $B$ ,  $\sharp A\flat + C - \sharp E\flat$  with  $f\sharp$ , which occur in the tetrachordals of minor scales already mentioned.

A *duodene*, then, consists of 12 tones, forming four *trines* of major Thirds arranged in three *quaternions* of Fifths. Hence the duodene constructed on the second tone C of any trine,  $\sharp A\flat + C + E$ , contains the *mapáma* or major of the first tone  $\sharp A\flat$ , the complete *decad* of the second tone C, and the *mipími* or common *descending* minor of the third tone E. It has therefore *three* tonics,  $\sharp A\flat$ , C, and E; but the tonic of the decad being most characteristic, this is called the *root* of the duodene, and the duodene is named after it.

Any duodene is clearly and sharply separated from its adjacent trines and quaternions, as shown in Table I., where the small innermost oblong marks off the duodene of C. For in the duodene the smallest intervals between two adjacent tones are the Semitone,  $\frac{16}{15}$ , ( $f\sharp$  to G, B to C, E to F,

<sup>1</sup> The justification of these chords is that the interval  $f$  to  $\sharp d\sharp = 2 \cdot \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2} \div \frac{1}{2} = \frac{1}{2} \cdot \frac{1}{2} \cdot \frac{1}{2}$ , and is hence very nearly the interval of the natural Seventh =  $\frac{1}{2}$ .

D to  $\sharp E\flat$ , G to  $\sharp A\flat$ , C to  $d\flat$ ); the Sharp,  $\frac{135}{128}$ , (F to  $f\sharp$ ,  $d\flat$  to D); and the low Sharp,  $\frac{25}{24}$ , ( $\sharp B\flat$  to B,  $\sharp E\flat$  to E,  $\sharp A\flat$  to A). But if we take the trine above,  $\sharp f + \sharp a + c\sharp$ , we have two intervals of a comma,  $\sharp$ , (F to  $\sharp f$ , A to  $\sharp a$ ), and one of a diaskhisma,  $\sharp\flat$ , ( $c\sharp$  to  $d\flat$ ). If we take the trine below,  $g\flat + b\flat + \sharp d$ , we have the same intervals of a comma ( $b\flat$  to  $\sharp B\flat$ ,  $\sharp d$  to D), and a diaskhisma ( $f\sharp$  to  $g\flat$ ). If we take the quaternion to the right, as  $\sharp c\sharp \times \sharp g\sharp \times \sharp d\sharp \times a\sharp$ , we have three intervals of a diesis,  $\sharp\sharp\flat$ , ( $a\sharp$  to  $\sharp B\flat$ ,  $\sharp d\sharp$  to  $\sharp E\flat$ ,  $\sharp g\sharp$  to  $\sharp A\flat$ , and  $\sharp c\sharp$  to  $d\flat$ ); and similarly if we proceed to the left. Hence the intervals introduced by adjacent trines and quaternions are all less than two commas. In equal temperament no new intervals would be thus introduced; for all the Fifths are there so altered that the new upper trine, tempered  $\sharp f + \sharp a + c\sharp$ , would become *identical* with the original bottom trine, tempered  $d\flat + F + A$ , except in order of terms; and the new quaternion to the right, tempered  $\sharp c\sharp \times \sharp g\sharp \times \sharp d\sharp \times a\sharp$ , would be *identical* both in value and order of terms with the old quaternion to the left, tempered  $d\flat \times \sharp A\flat \times \sharp E\flat \times \sharp B\flat$ . The consequence is that *only one duodene* exists for equal temperament, and the real nature of modulation is thoroughly disguised. In tertian temperament this would not be the case; the quaternions would be distinguished, but the trines would partly coincide, and hence some, but not all, of the meaning of modulation would be lost<sup>1</sup>.

<sup>1</sup> If in Table I. the signs  $\sharp \flat$  be omitted, and the letters and the signs  $\sharp \flat$  be taken to have their values in Tertian or any uniform commatic temperament (except the Equal, which is also skhismatic), the Table will represent the corresponding duodenes. But if the letters and signs  $\sharp \flat$  are taken to have their value in the Equal temperament, so that

C	D	E	F	G	A	B
=Dbb	Ebb	Fb	Gbb	Abb	Bbb	Cb
and =B $\sharp$	C $\sharp\sharp$	D $\sharp\sharp$	E $\sharp$	F $\sharp\sharp$	G $\sharp\sharp$	A $\sharp\sharp$

and

O $\sharp$	D $\sharp$	E $\sharp$	F $\sharp$	G $\sharp$	A $\sharp$	B $\sharp$
=Db	Eb	F	Gb	Ab	Bb	C

(showing the utterly absurd relations between symbolization and signification), then the same Table will reduce to the one central duodene with its tones differently distributed. This will be still better shown by using

C od D de E F fg G ga A ab B

for the 12 digitalis on a piano, so that the central duodene and its adjacent trines and quaternions reduce to

od	F	A	od	F
fg	ab	D	fg	ab
B	de	G	B	de
E	ga	C	E	ga
A	od	F	A	od
D	fg	ab	D	fg

In skhistic intonation, the modification of the Fifth leads to a modification of the comma and obliteration of the skhisma; so that the two first tones, skhistic  $\sharp f$ ,  $\sharp a$ , of the new upper trine,  $\sharp f + \sharp a + c\sharp$ , are *one skhistic comma higher*, and the third, skhistic  $c\sharp$ , is *one skhistic comma lower* than the two last tones,  $F$ ,  $A$ , and the first tone  $D\flat$  of the old trine,  $D\flat + F + A$ . And the tones of the new right quaternion will be in the same order, exactly *two skhistic commas flatter* than the old left-hand quaternion<sup>1</sup>.

The consequence is that if we took 4 *independent* duodenes (that is, such that no tone of one is common to any tone of the other) as the duodenes of  $\sharp B\flat$ ,  $A\sharp$ ,  $G\flat$ , and  $\sharp F\sharp$ , the tones of which are contained within the dotted lines and right side of the inner oblong of Table I., the tones of the duodenes  $A\sharp$  and  $\sharp F\sharp$  will be two commas flatter than those of  $\sharp B\flat$  and  $G\flat$ ; and the tones of the *two first* quaternions of the  $\sharp B\flat$  and  $A\sharp$  duodenes will be one comma *sharper* than those of the *two last* quaternions of  $G\flat$  and  $\sharp F\sharp$ , while the tones of the *third* quaternions of  $\sharp B\flat$  and  $A\sharp$  will be one comma *flatter* than those of the duodenes of  $G\flat$  and  $\sharp F\sharp$  respectively.

The result, then, is that the 48 tones will consist of four corresponding sets of 12 tones each appearing in 4 forms, differing in pitch by one skhistic comma. This will appear more clearly by the following Table, in which the value in octs of the cycle of 301 is given for 73 tones, being those in cols. I. to VI. of Table I., less those in col. I., lines  $l$ ,  $m$ ,  $n$ , and col. VI., lines  $y$ ,  $z$ . The 48 of those tones contained in 4 independent duodenes are in Roman capitals, the other of the 73 tones, which are some of their skhistic synonyms, are in Roman small letters, and other synonyms are added in *Italics*; the whole are divided into groups of 4, the constituents of which differ from one another by 5 octs, or one skhistic comma.

<sup>1</sup> This is readily seen by expressing the tones in terms of the octs of the cycle of 301, by continually adding and subtracting 176 for the Fifths and 97 for the major Thirds, adding or subtracting 301 as often as is necessary to reduce to the same Octave. A skhistic comma is represented by 5 octs. This gives

Tones.					Octs.

Since, then, the duodene of C is precisely adapted for placing on our ordinary manuals, and no corresponding tones which have to be introduced within these limits will be more than two or three commas sharper or flatter than these, such corresponding tones (owing to our habits of reading musical notes into directions for using digitals) will be all fitted for being played on the same digitals. This is the most important point in the practical construction of instruments, and is for the first time pointed out in this paper.

Another important result is, that if we take any 12 consecutive skhistic tones in order of Fifths, or 8 consecutive tones in that order, and 4 others separated from them by 24 or 48 Fifths, although such tones will not form a duodene, they will be 12 tones suitable for our manuals, and will therefore afford the means of temporarily supplementing other arrangements.

In skhistic intonation, then, the modulational peculiarities of just intonation are preserved; and it will be convenient in future to consider modulation as taking place by duodenes, and hence consisting of *duodenation*. We shall therefore have in just intonation both vertical and lateral duodenation to consider; but in skhistic intonation it will be seen by Table II. that *one right lateral duodenation*, as from root †B<sup>b</sup> to root D, is the same as *eight descending vertical duodenations*, for these would in just intonation lead to the root E<sup>b</sup><sup>b</sup>, which, as shown in the last Table, is skhistically identical with D. Hence in skhistic intonation we have, so far as instruments are concerned, only to render vertical duodenation possible and easy.

And in writing music, if we note at the top of any bar the name of the duodene to which the notes to be played belong, and suppose this *duodenal* (as the mark may be called, in contradistinction to the *signature*, which will remain as before) to hold till a new one is written (according to the custom of musical signatures), we shall be able precisely to mark the pitch of every tone in just or skhistic intonation, *without introducing any change or any additional sign into the staff-notation of music*<sup>1</sup>. This is again an entirely new practical principle resulting from the present theory. The duodenal will direct the player to the mode of arranging the manual he has to use. It should be the duty of the composer to insert the duodenals himself; but in respect of existing compositions, which were composed for some commatic system of temperament, it will be often difficult to determine which of two adjacent vertical duodenes it would be best to use; and it will probably be necessary to introduce commatic changes, when they can be made within the limits of a single heptadecad. Also in the case of compositions in a *major* scale, which do not change into the minors of the same decad, and hence use only two quaternions of a duodene, but will necessarily and frequently modulate to the right, it is more convenient to consider the music as performed in the first and second quaternions of a duodene having for its root the Third of the major scale, because the third quaternion of that duodene contains the tones required for right lateral modulation. Thus C major will be assigned to the duodene of E, No. 19 of Table II., and F major to the duodene of A, No. 20 of Table II., &c. This makes the modulation from the major into the relative minor as simple and direct as vertical modulation, for C major passes into any form of A minor or major by descending vertically from the duodene of E to that of A. All pieces in any minor scale pass into each of the three quaternions of a duodene, and hence their duodenal will be the tonic of their decad, which gives its name to the duodene. The duodene is then prepared for playing the synonymous major of that minor scale. Such duodenals might be distinguished by an added star.

It often happens that passing tones, changing notes and *appoggiature*, are introduced which do not belong to the harmony. They are written usually after the laws of Pythagorean temperament, but their pitch is really indeterminate. For these there is no occasion to change the duodenal at all. They will then be played in the duodene of the other

<sup>1</sup> For theoretical and experimental purposes it may be sometimes convenient to use signs equivalent to † ‡ in the staff-notation itself. The signs † ‡ for †, ††, and ‡ for ‡, ‡‡, being the tails of quavers and semiquavers, are well adapted for this purpose. The direction of the angles show ascent and descent, and the forms exist as types for every required position on the staff; thus †a, †d, †bb, and ‡g♯, would be

harmonies by a tone of not more than two commas different, which must be considered as their proper representative in just intonation.

*E. Number of Tones required.*

The next important point is to determine how many duodenes must be provided. In Table I. the large *inner* oblong contains all the duodenes which have at least *one* tone in common with the original duodene of C. Thus the duodenes  $\dagger D\flat$  and  $\ddagger B$  have respectively the tones  $\dagger B\flat$  and A in common with the original duodene, and no others. If we proceeded further, as vertically from the  $\dagger D\flat$  to the  $\dagger\dagger A\flat$  duodene, we should no longer have any connexion with the decad of the original tonic C. The confusions of modern equal temperament might lead much further; but in that case we must restore the commatic changes which equal temperament ignored, considering, for example, that when the composer modulated into tempered  $A\flat$  from tempered  $D\flat$  he really meant to make a modulation from just  $D\flat$  into just  $\dagger A\flat$ , and not from  $\dagger D\flat$  to just  $\dagger\dagger A\flat$ . It would probably have never been the composer's intention to proceed to such unrelated duodenes as these two last.

The limits of the *original roots* of duodenes may be taken to be the tones of the duodene of C. Practically, composers had no others in their minds. Any smaller changes of pitch were relegated to differences in the pitch of C, whence all the others were derived. If, then, we construct the limiting duodenes to the extreme tones of the duodene of C as original roots, we shall obtain all the tones in Table I., being  $9 \times 13 = 117$  in number. This is the number of tones required, therefore, in just intonation.

Skhistic intonation would introduce identifications which would reduce this number to the  $9 \times 8 = 72$  tones in the lines *p* to *x* in Table I., together with *three* in col. 1, lines *l*, *m*, *n*, and *two* in col. 9, lines *y* and *z*, that is to 77 skhistic tones in all. The last 5 are so extremely unlikely to occur, however, that we may consider these 72 skhistic tones as sufficiently representing the whole 117 of the Table. These 72 tones form 6 independent duodenes, those of  $\dagger\dagger E\flat\flat$ , D and  $\ddagger C\sharp\sharp$ , and of  $\dagger C\flat\flat$ ,  $B\flat$  and  $\ddagger A\sharp$ . It will be shown that there is really no difficulty in playing them all, with existing means, if required; but they would not be required. The tendency of musicians is not to modulate to both right and left equally in the same piece. It has been already noted that on account of the prevalence of major scales duodenation is generally to the right. The fingering for the duodenes of  $\dagger B\flat$  and  $A\sharp$  would be the same on manuals constructed on the duodenary theory, although the tones in skhistic intonation would differ by two skhistic commas. If, then, a piece in  $\dagger B\flat$  duodenated much to the left, that is (for skhistic intonation), ascended vertically, we could play it as  $A\sharp$ . It would simply be necessary to write  $\ddagger B\flat$  as its duodenal, as that is shown to be identical with  $A\sharp$  in the last Table. We should then be able to use ascending duodena-

tion with great ease, as shown in Table II., even if columns 1 and 2 in Table I. were omitted. Hence we may begin by cancelling columns 1 and 2 of Table II. In view of the greater frequency of right lateral or descending duodenation, we need only reject column 9 to the right<sup>1</sup>. We have thus reduced the just tones to the  $6 \times 13 = 78$  in columns i. to vi. of Table I. The skhistic identifications reduce these further to the  $6 \times 8 = 48$  tones in lines *p* to *x* of the same columns, together with the three tones in col. i., *l*, *m*, *n*, and the two in col. vi., *y*, *z*. As these tones may, I think, be always avoided by properly choosing the original root, motives of convenience induce me to reduce the number of skhistic tones necessary to the 48 included by the dotted lines in cols. i. to vi. of Table I.

In my former paper ('Proceedings,' vol. xiii. p. 98), not having taken a sufficiently comprehensive view of the nature of modulation, I fixed the number of just tones required at 72 instead of 117, and showed that they would reduce by skhismatic substitution (for I had not then worked out the theory of skhistic temperament) to 45; and on examination it will be found that these 45 include the 48 which I have just named, with the exception of those in col. i., lines *p* and *q*, and col. vi., line *x* of Table I. The tones used in Mr. Liston's organ (according to the statement I was able to give in 'Proceedings,' vol. xiii. p. 417, note §), on being treated skhistically, include 44 of these 48 tones, omitting the 4 tones in col. i., lines *w*, *x*, col. v., line *x*, and col. vi., line *x*, and introduces two others found in col. 2, lines *p* and *x*, and probably only due to his system of tuning. He has thus 46 tones in all. Gen. T. Perronet Thompson's organ (see my paper in 'Proceedings,' vol. xiii. p. 102), when similarly reduced, has 38 of my 48 tones, omitting all col. i., col. ii., line *x*, and col. vi., line *r* in Table I., and retaining the two tones of col. vi., lines *y*, *z*, which I do not find necessary. Mr. Poole's latest organ (Silliman's Journal for 1867, pp. 1 to 45), after rejecting his 39 natural Sevenths, which I expressly exclude, has 61 just tones, which reduce to the 36 skhistic tones in col. ii., lines *q* to *x*, cols. iii., iv., and v., lines *p* to *x*, and col. vi., lines *p* to *t*. These are the principal attempts at limiting the scale actually made up to this time; and hence I conclude that my reduction to 48 skhistic tones (that is, practically, unequally just tones) would embrace almost every case, though it is conceivable that some extraordinary music might make it advisable to introduce 12 more, namely, col. 2, lines *p* to *x*, and col. 9, lines *p* to *s*, making 60 tones in all, for adding which provision should be made.

<sup>1</sup> If in changes of key in the movements of a long piece modulation took place first much to the left and then much to the right, we might perhaps make commatic changes between the movements, without disturbing the connexion. And when changes are introduced by successions of discords, such commatic changes could not be observed at all by the listener. By the use of the duodenal, however, they will be rendered perfectly simple to the performer.

The 48 tones thus pointed out form the 32 trines, which, with their skhistic synonyms, are shown on Table II. By taking these in quaternions we obtain 29 duodenes. In Table II. the root of the duodene is written against its uppermost trine, and hence the root itself is found in the middle of the second trine below, and the whole duodene extends to the third trine below. Trines on the same line are skhistically identical, the capitals indicating the names of the 48 selected tones of cols. I. to VI., lines *p* to *x*, in Table I. In Table III. the roots of these duodenes are arranged in 4 columns, of which each tone in the same line is skhistically identical; but, proceeding from left to right, each tone is, in just intonation, one skhisma flatter than the next adjacent tone on the right.

In Table III., also, the tones in each of the duodenes are written down in the order in which they would stand on a manual; but the skhistic identities of the central column of tones in the preceding Table of Octs (p. 19) have been used to give the same names to all the tones in one column, exclusive of the prefixed † and ‡. We thus see clearly that three new tones are introduced by each new successive duodene, two falling and one rising by a skhistic comma, as respects the tones they replace. We also see that each tone prevails through 4 consecutive duodenes, and that there are 4, and only 4, varieties of †, ‡ in each column.

This completes the *theory* of the construction of instruments, because the rest is properly the work of the mechanician, and consists simply in devising a method for bringing each of these 29 duodenes under the hand of the performer, when indicated by the duodenal. It will be sufficient here to point out a few experimental instruments, to suggest some practical forms, and to show that means of playing in just intonation with fixed tones already exist.

#### F. Justly or Skhistically Intoned Instruments.

1. *Just Concertina* (exhibited when this paper was read). The C concertina described in my former paper (Proceedings, vol. xiii. p. 104) contains the portion of a heptadecad shown in the margin—that is, the duodene of E with the exception of A♯, and the duodene of A with the exception of †F♯. It has the whole decad of E, and the major scales of F, C, G, E. I have found it a most useful instrument in all my experiments. Using capitals for white and small letters for black studs, its 14 notes are tuned thus:—

C ‡c♯, D ‡d, E ‡d♯, F f♯, G ‡g♯, †A a, B b♭.

2. *Just Harmonium* (exhibited when this paper was read). For

ordinary lecture and illustrative purposes, this is the cheapest and best instrument. It contains the portion of a heptadecad shown in the margin, and hence contains the duodene of C with the exception of F $\sharp$ , the whole decad of C, and the major scales of  $\dagger E\flat$  and  $\dagger A\flat$ . The two last show vertical modulation. Again,  $\dagger E\flat$  major or  $\dagger A\flat$  major to C decad shows right lateral, and, inversely, C decad to  $\dagger E\flat$  major or  $\dagger A\flat$  major shows left lateral modulation. The F and  $\dagger F$  show the influence of a comma, and the difference between the just triad,  $D\flat + F - \dagger A\flat$ , and the Pythagorean triad,  $D\flat$  with  $\dagger F$  and  $\dagger A\flat$ . Also in the key of  $\dagger E\flat$  major the difference can be shown between the minor chord,  $F - \dagger A\flat + C$ , and the chord of the added Sixth,  $\dagger A\flat + C \mid \dagger F$ . It also contains the German Sixth,  $D\flat + F - \dagger A\flat$  with B (which is a close imitation of the chord of the natural Seventh), the Italian Sixth,  $D\flat + F$  with B, and the French Sixth,  $D\flat + F \dots G + B$ . Using capitals and small letters for the black and white keys, they are arranged thus :—

C  $d\flat$  D  $\dagger e\flat$  E F  $\dagger f$  G  $\dagger a\flat$  A  $\dagger b\flat$  B.

The  $\dagger F$  is placed on the F $\sharp$  digital, and the fingering is normal in other respects. The five tones,  $d\flat \times \dagger a\flat \times \dagger e\flat \times \dagger b\flat \times \dagger f$ , will then enable us to play all Scotch and other music containing only five tones, in perfectly just intonation, on the black digitals, and to show that such music cannot be harmonized. The practical direction for tuning is, "tune the following 7 major chords without beats, putting  $\dagger F$  on the F $\sharp$  digital, F A C, C E G, G B D;  $D\flat$  F  $\dagger A\flat$ ,  $\dagger A\flat$  C  $\dagger E\flat$ ,  $\dagger E\flat$  G  $\dagger B\flat$ ,  $\dagger B\flat$  D  $\dagger F$ ." A four-Octave instrument was thus tuned in two hours.

3. *Hephtharmonium*. This requires two rows of vibrators and Mr. Saunders's "tilting action," already described. The vibrators are disposed thus :—

*Back* ....  $\dagger D\flat$   $\dagger c\sharp$   $\dagger D$   $\dagger d\sharp$   $\dagger E\flat$   $\dagger F$   $\dagger f\sharp$   $\dagger G\flat$   $\dagger g\sharp$   $\dagger A$   $b\flat$   $\dagger C\flat$   
*Front* .... C  $d\flat$  D  $\dagger e\flat$  E F  $f\sharp$  G  $\dagger a\flat$  A  $\dagger b\flat$  B.

This harmonium contains all the tones in a heptadecad (whence its name), and consequently illustrates every kind of modulation in the first degree, and becomes a most valuable instrument for the lecturer and teacher of singing. The front vibrators, to which correspond the digitals when the stops are all pushed in, contain the whole duodene of C, and the stops enable the player to exchange their tones for those in the six other decads. All lie on the usual digitals except  $\dagger D\flat$  and  $\dagger G\flat$ , which are placed on the long white digitals of C and G, in place of the short black digitals next to their right, as these were wanted for  $\dagger c\sharp$  and  $\dagger g\sharp$ . This makes a slight difference in the fingering of  $\dagger E\flat$  minor and similar scales.

4. *Helmholtz's Harmonium* (Tonempfindungen, p. 496). Two sets of vibrators are tuned, the back set to the duodene of  $E\flat$  or  $D\sharp$ , No. 14, Tables II. and III., and the front set to duodene of  $\sharp C\flat$  or B, No. 18, of the same. This instrument contains the eight trines, Nos. 14 to 21, and the five duodenes, Nos. 14 to 18, Table II. The "tilting action" produces a most useful experimental instrument, which is far easier to use than Helmholtz's own double manual instrument, because it has only one manual, and requires no alteration in ordinary fingering. For this purpose the stops may be reduced to four, each changing a trine instead of a single note.

5. *Guérout's Harmonium* (Comptes Rendus, 1872, p. 1188). This, again, may be treated as the last by means of Mr. Saunders's "tilting action." Two sets of vibrators must be used, the back set tuned to duodene  $\sharp D\flat$  or  $C\sharp$ , No. 16, and the front to  $\sharp B\flat\flat$  or A, No. 20, of Tables II. and III. M. Guérout tuned the  $B\sharp$  of duodene No. 16 as  $B\sharp = \frac{54638}{54675} B\sharp$ , so as to make the combinational tone of  $G\sharp$  and  $B\sharp$  the same as that of  $B\sharp$  and  $E\flat$ , the other tones being tuned in just intonation from C. Omitting this as unnecessary, the instrument contains the eight trines, Nos. 16 to 23 of Table II., and the five duodenes, Nos. 16 to 20. M. Guérout arranged the tones somewhat differently for two manuals.

6. *Duóni, Trióni, Quartóni, Quintóni, Sestóni*. The Russian horn-band which visited London some years ago, and produced great effects by each performer's playing a single tone only (and hence, probably, in just intonation), and the customs of hand-bell and church-bell ringers, who each play a single note in a melody, have suggested to me the use of *two, three, four, five, or six* harmoniums or pianofortes, indicated by the above names, for the purpose of playing in skhistic or unequally just intonation, by means of two, three, four, five, or six performers, among whom the tones are distributed. The *Duóni* are intended for two independent duodenes, as in the two last cases, the *Quartóni* for four such, playing the whole 48 tones, the *Sestóni* for six, in the almost impossible case of 72 tones being required. The *Trióni* supplement the *Duóni* by using 12 additional tones, forming consecutive Fifths, and hence not constituting a duodene, by which means the 36 tones of Mr. Poole's compass can be played. The *Quintóni* supplement the *Quartóni* in a similar manner; but the first 8 tones are those in col. 2, lines  $p$  to  $x$ , and the last 4 those in col. 9, lines  $p$  to  $s$  of Table II.—giving 60 tones on the whole, chosen so as to supplement without changing the arrangement of the *Quartóni*.

In each case separate harmoniums or pianos are used, with no change in existing mechanism or fingering, but only in intonation; so that the instruments could be obtained and tuned in unequally just intonation, as

already described, without difficulty, at a day's notice. The music is to be marked with the proper duodenals, and the duodenes thus indicated are to be transcribed separately, and divided into parts by transverse lines, corresponding to the tones existing on the different instruments. The copyist writes out a separate part for each performer (which had better have an indication of the complete harmony annexed), in which only those notes that belong to his own instrument are written. Thus, suppose that the duodene is F $\sharp$ , and the lines show what tones lie on

(II.)  $\dagger E$  G $\sharp$  B $\sharp$  the instrument (I., II., III.), as in the margin. Suppose that the succession of chords  $e\sharp g\sharp b' e''\sharp, f\sharp e'\sharp a'\sharp e''\sharp$ , and  $B \dagger d'\sharp f\sharp b'$  (I.)  $\dagger A$  C $\sharp$  E $\sharp$  (III.) has to be played. The tones will be distributed as in the margin. Considerable practice

would be necessary to take up the notes truly at the right moment, but

(I.)  $\left\{ \begin{array}{l} e''\sharp \\ b' \end{array} \right\} \left\{ \begin{array}{l} e'\sharp \\ e'\sharp \\ f\sharp \end{array} \right\} \left\{ \begin{array}{l} b' \\ f'\sharp \\ B \end{array} \right\}$  there is no longer any instrumental or digitational difficulty in playing in just intonation.

(II.)  $g\sharp$  — — Leaving *Duóni* aside as sufficiently indicated in the two last cases, and of only experimental interest, and *Sestóni* as practically not required, (III.)  $e\sharp a'\sharp \dagger d'\sharp$  it will be enough to explain the tuning of *Trióni*, *Quartóni*, and *Quintóni*.

*Trióni*. Tune the three instruments thus :—

(I.) C  $\dagger d\flat$  D  $\dagger e\flat$  E  $\dagger F$   $\dagger g\flat$  G  $\dagger a\flat$   $\dagger A$   $\dagger b\flat$  B  
 (II.)  $\dagger C$   $d\flat$   $\dagger D$   $e\flat$   $\dagger E$  F  $g\flat$   $\dagger G$   $a\flat$  A  $b\flat$   $\dagger B$   
 (III.)  $\dagger B\sharp$   $\dagger c\sharp$   $\dagger C\sharp\sharp$   $\dagger d\sharp$   $\dagger E$  E $\sharp$   $\dagger f\sharp$   $\dagger F\sharp\sharp$   $\dagger g\sharp$   $\dagger G\sharp\sharp$   $a\sharp$   $\dagger B$

Then (I.) is in the duodene of G, No. 10, and (II.) in that of E $\flat$ , No. 14 of Tables II. and III.; and this readily gives the method of tuning them. (III.) consists of 12 tones forming consecutive Fifths from E $\sharp$  to  $\dagger E$ , col. 7, lines  $q$  to  $y$ , and from  $\dagger G\sharp\sharp$  to  $\dagger B\sharp$ , col. 8, lines  $q$  to  $t$  of Table I. For (III.) begin by tuning  $\dagger G\sharp$  a major Third without beats to E in (I.), and then work up to E $\sharp$  and down to  $\dagger E$  by Fifths, verifying with the corresponding major Thirds below in (I.) and (II.). Then tune  $\dagger B\sharp$  a major Third above  $\dagger G\sharp$ , and tune up by Fifths to  $\dagger G\sharp\sharp$ , verifying by the major Thirds below, which lie all in (III.). By this the three instruments are completely in tune, and give the 17 duodenes, Nos. 10 to 26, Table II., containing Mr. Poole's scale of 36 tones.

*Quartóni* are much simpler, because they contain the four independent duodenes,

(I.) of  $\dagger B\flat$ , No. 1,

(III.) of A $\sharp$ , No. 25,

(II.) of G $\flat$ , No. 5,

(IV.) of  $\dagger F\sharp$ , No. 29

Table III., where the corresponding lines give the tuning of each

instrument. The arrangement of tones is managed as before. Suppose, for example, we have to play the succession of chords  $e g c' g'$ ,  $f f c' a'$ ,  $d g f' b'$ , and  $c g e' c'$  in the duodene of C, this duodene would be written and the tones would be distributed among the four instruments as follows :—

(I.)	$\sharp B\flat$ $\sharp E\flat$	D G		$F\sharp$ B	(III.)	(I.)	$g g'$	—	$g d$	$g$
						(II.)	$c$	$c' f$	$f$	$c c'$
						(III.)	—	—	$b'$	—
(II.)	$\sharp A\flat$ D	C F		E A	(IV.)	(IV.)	$e$	$a'$	—	$e'$

*Quintóni* have five instruments, (I.) to (IV.) being tuned as in *Quartóni*, and (V.) added when by some extraordinary vagaries of modulation more than 48 tones are needed. (V.) is tuned thus, where the synonyms show the meaning of the arrangement :—

(V.)  $\sharp D\flat\flat$   $\flat b\sharp\sharp$   $\sharp\sharp E\flat\flat$   $\flat f\flat\flat$   $\sharp\sharp F\flat$   $\flat G\flat\flat$   $\flat e\sharp\sharp$   $\sharp\sharp A\flat\flat$   $\flat f\sharp\sharp\sharp$   $\sharp\sharp B\flat\flat$   $\flat c\flat\flat$   $\flat A\sharp\sharp$   
 $=\sharp\sharp C$   $\flat\flat c\sharp$   $\sharp\sharp D$   $\flat\flat e\flat$   $\sharp\sharp\sharp E$   $\sharp\sharp F$   $\flat\flat f\sharp$   $\sharp\sharp G$   $\flat\flat g\sharp$   $\sharp\sharp\sharp A$   $\flat\flat b\flat$   $\flat\flat B$

The tuning of (V.) is effected thus :—Tune  $\sharp\sharp A\flat\flat$  as a major Third below  $\sharp C\flat$  on (I.), and then work up by Fifths to  $\sharp\sharp F\flat$  and down to  $\flat F\flat\flat$ , verifying by the major Thirds above in (I.) and (II.). Then tune  $\flat A\sharp\sharp$  as a major Third above  $\flat F\sharp\sharp$  in (III.), and work up by Fifths to  $\flat F\sharp\sharp\sharp$ , verifying by the major Thirds below in (III.). The notation of the tones, though inevitable, is frightful; but the tuning is very simple, and the use of the duodenal leaves the old staff-notation unchanged. It is most probable that the fifth instrument would never be wanted.

7. *Great and Small Duodenary Harmonium.* Although the mode just explained places just intonation at the immediate command of three or four performers, yet it seems necessary to suggest a mode of putting all the 17 or 29 duodenes at the command of a single performer. I suggest the following for consideration. It seems practicable, but would doubtless require much mechanical treatment from harmonium-builders before it would act properly. It will be enough to indicate the form of the great duodenary.

Take four sets of vibrators, tuned as for *Quartóni*, and placed one behind the other, each opening with a separate valve connected with a digital. Sometimes two digitals will have to be connected with the same valve. Conceive the manual as a set of 29 “steps,” with  $\frac{3}{4}$ -inch “tread” and  $\frac{1}{4}$ -inch “rise,” the lowest step next the performer. Each step for the length of an Octave is divided into 12 digitals corresponding to the columns in Table III. The width of

the digitals to be as follows for No. 11 of Table III., in *eighths of an inch* :—

C	dp	D	tep	E	F	igp	G	tap	A	tpb	B
5	3	5	3	5	5	3	5	3	5	3	5

The digitals corresponding to the small letters are to rise  $\frac{1}{4}$  inch above the others and to be bevelled, so that they are  $\frac{3}{8}$  inch wide at bottom, and  $\frac{1}{4}$  inch wide at top. Each step is then a miniature finger-board in the ordinary arrangement. Whenever any note occurs in 4 consecutive steps, as shown by the cross lines in Table III., its 4 digitals are to be consolidated into one, so that, except in "steps" 1 to 3 and 26 to 29, the digitals will be practically 3 inches long. To show which digitals are consolidated, colour the low wide digitals alternately white and light red, and the high narrow digitals alternately light blue and light brown, distinctions of colour easily seen. To mark the duodene, draw a black line,  $\frac{1}{4}$  inch broad, across the digital bearing the name of the duodene, and put a black circle of  $\frac{1}{4}$  inch in diameter on the tonic of the major scale which it contains. The lines thus marked, together with the alternation of colour, will clearly distinguish each duodene.

The depth of this manual from front to back would be  $21\frac{1}{2}$  inches, and the rise  $7\frac{1}{2}$  inches; the width of an Octave from *C* to *B* is  $6\frac{1}{2}$  inches, and from *C* to *c* is  $6\frac{1}{2}$  inches. This last width is  $7\frac{3}{4}$  inches on the piano; but as the hand would on the duodenary always have to dip between high digitals to strike Octaves of low digitals, it must be held more upright, and hence its span will be less. A manual of five Octaves and one note, *C* to *c'''*, will be  $31\frac{1}{2}$  inches long. The number of movable digitals in each column of Table III. is 8, which open only 4 valves; this will necessitate coupling—the details resulting from Table III., which may be considered as a ground-plan of this manual<sup>1</sup>.

<sup>1</sup> When this paper was read I mentioned that the 48 tones, making 29 duodenes, of Tables II. and III. could be played on Mr. Bosanquet's "generalized key-board," as exhibited to the Royal Society when his paper was read on January 30, 1873, with less difficulty in mechanism than by the plan I proposed (of which a model was exhibited), but that slightly new fingering would then be necessary; and also that the 72 tones of Table I., lines *p* to *x*, making 53 duodenes, might be played by the same arrangement on a manual not larger than that which I proposed for the 48 tones or 29 duodenes; and hence that the sole advantage of my scheme for a manual was its preservation of the present fingering, against which had to be set off the advantage that the new fingering of Mr. Bosanquet would be the same in all keys or duodenes. The intonation, however, would remain different from Mr. Bosanquet's.

The tones in the *small* central oblong form the duodene of which C is the root.

The tones in the *large* central oblong form all the duodenes which have at least one tone in common with the central duodene of C, forming the limits of radical duodenation from C.

The complete Table contains all the duodenes which have at least one tone in common with duodenes whose roots are tones in the duodene of C, forming the limits of general radical duodenation.

The 48 tones in columns I. to VI., between the dotted lines, are those considered sufficient for instruments with fixed tones in skhistic or unequally just intonation.

*November 26, 1874.*

W. SPOTTISWOODE, M.A., Treasurer and Vice-President, in the Chair.

In pursuance of the Statutes, notice was given from the Chair of the ensuing Anniversary Meeting, and the list of Officers and Council proposed for election was read as follows :—

*President.*—Joseph Dalton Hooker, C.B., M.D., D.C.L., LL.D.

*Treasurer.*—William Spottiswoode, M.A., LL.D.

*Secretaries.*— { Prof. George Gabriel Stokes, M.A., D.C.L., LL.D.  
 { Prof. Thomas Henry Huxley, LL.D., Ph.D.

*Foreign Secretary.*—Prof. Alexander William Williamson, Ph.D.

*Other Members of the Council.*—Prof. J. Couch Adams, LL.D.; the Duke of Devonshire, K.G., D.C.L.; Capt. Frederick J. O. Evans, R.N., C.B.; John Evans, Pres. G.S., F.S.A.; Albert C. L. G. Günther, M.A., M.D.; Daniel Hanbury, Treas. L.S.; Sir John Hawkshaw, Knt., M.I.C.E.; Joseph Norman Lockyer, F.R.A.S.; Robert Mallet, C.E., M.R.I.A.; Nevil Story Maskelyne, M.A.; C. Watkins Merrifield, Hon. Sec. I.N.A.; Prof. Edmund A. Parkes, M.D.; Right Hon. Lyon Playfair, C.B., LL.D.; Andrew Crombie Ramsay, LL.D.; Major-Gen. Sir H. C. Rawlinson, K.C.B.; J. S. Burdon Sanderson, M.D.

The Presents received were laid on the table, and thanks ordered for them.

The following Paper was read :—

“ Preliminary Notes on the Nature of the Sea-bottom procured by the Soundings of H.M.S. ‘ Challenger ’ during her Cruise in the ‘ Southern Sea ’ in the early part of the year 1874.” By Professor C. WYVILLE THOMSON, F.R.S., Director of the Civilian Scientific Staff on Board. Received Nov. 12, 1874.

[Plates I.—IV.]

During our southern cruise the sounding-lead brought up five absolutely distinct kinds of sea-bottom, without taking into account the rock and detritus of shallow soundings in the neighbourhood of land. Our first two soundings in 98 and 150 fathoms, on the 17th and 18th of December, were in the region of the Agulhas current. These soundings would have been naturally logged “ greenish sand ;” but on examining the sandy particles with the microscope, they were found to consist almost without exception of the casts of Foraminifera in one of the complex silicates of alumina, iron, and potash, probably some form of glauconite.

The genera principally represented by these casts were *Miliola*, *Biloculina*, *Uvigerina*, *Planorbulina*, *Rotalia*, *Textularia*, *Bulimina*, and *Nummulina*; *Globigerina*, *Orbulina*, and *Pulvinulina* were present, but not nearly in so great abundance. There were very few Foraminifera on the surface of the sea at the time. This kind of bottom has been met with once or twice before; but it is evidently exceptional, depending upon some peculiar local conditions.

From the Cape, as far south as our station in lat.  $46^{\circ} 16'$ , we found no depth greater than 1900 fathoms, and the bottom was, in every case, "*Globigerina*-ooze;" that is to say, it consisted of little else than the shells of *Globigerina*, whole, or more or less broken up, with a small proportion of the shells of *Pulvinulina* and of *Orbulina*, and the spines and tests of Radiolarians and fragments of the spicules of Sponges.

Since the time of our departure, Mr. Murray has been paying the closest attention to the question of the origin of this calcareous formation, which is of so great interest and importance on account of its anomalous character and its enormous extension. Very early in the voyage, he formed the opinion that all the organisms entering into its composition at the bottom are dead, and that all of them live abundantly at the surface and at intermediate depths, over the *Globigerina*-ooze area, the ooze being formed by the subsiding of these shells to the bottom after death.

This is by no means a new view. It was advocated by the late Professor Bailey, of West Point, shortly after the discovery, by means of Lieutenant Brooke's ingenious sounding-instrument, that such a formation had a wide extension in the Atlantic. Johannes Mueller, Count Pourtales, Krohn, and Max-Schultze observed *Globigerina* and *Orbulina* living on the surface; and Ernst Haeckel, in his important work upon the Radiolaria, remarks "that we often find upon, and carried along by the floating pieces of sea-weed which are so frequently met with in all seas, Foraminifera as well as other animal forms which habitually live at the bottom. However, setting aside these accidental instances, certain Foraminifera, particularly in their younger stages, occur in some localities so constantly, and in such numbers, floating on the surface of the sea, that the suspicion seems justifiable that they possess, at all events at a certain period of their existence, a pelagic mode of life, differing in this respect from most of the remainder of their class. Thus Müller often found in the contents of the surface-net off the coast of France, the young of *Rotalia*, but more particularly *Globigerina* and *Orbulina*, the two latter frequently covered with fine calcareous tubes, prolongations of the borders of the fine pores through which the pseudopodia protrude through the shell. I took similar *Globigerina* and *Orbulina* almost daily in a fine net at Messina, often in great numbers, particularly in February. Often the shell was covered with a whole forest of extremely long and delicate calcareous tubes projecting from all sides, and probably contributing essentially to enable these little animals to float below the surface

...common, and gave an interesting account for a family which should include *Globigerina* genus, and *Pulvinulina*, the name Colymbites like the Radiolaria, these Foraminifera are sunset, "diving" to some depth beneath it. Our colleague, Mr. Gwyn Jeffreys, chiefly Owen's papers, maintained that certain Foraminifera in opposition to Dr. Carpenter and myself†. a very strong opinion on the matter. It seemed conclusive that the Foraminifera which ooze lived on the bottom, and that the occurrence on the surface was accidental and exceptional; but carefully, and considering the mass of evidence related by Mr. Murray, I now admit that I was wrong. I told him that it may be taken as proved, that all the Foraminifera (with the exception of course of the remains of some which are known to live at the bottom at all depths, and with some foreign bodies) are derived from the surface.

Mr. Murray has combined with a careful examination a constant use of the tow-net, usually at the surface, from ten to one hundred fathoms; and he has been able to fix the difference between the surface-fauna of any particular locality and which is taking place at the bottom. In all the polar ice, the tow-net contains *Globigerina*. and of a larger size, in warmer seas; several species of size, and presenting marked varietal characters in the tropical area of the Atlantic. In the latitude of the numerous and smaller species.

and transparent, and each of the pores which penetrate it is surrounded by a raised crest, the crest round adjacent pores coalescing into a roughly hexagonal network, so that the pore appears to lie at the bottom of an hexagonal pit. At each angle of this hexagon the crest gives off a delicate flexible calcareous spine, which is sometimes four or five times the diameter of the shell in length. The spines radiate symmetrically from the direction of the centre of each chamber of the shell, and the sheaves of long transparent needles, crossing one another in different directions, have a very beautiful effect. The smaller inner chambers of the shell are entirely filled with an orange-yellow granular sarcode; and the large terminal chamber usually contains only a small irregular mass, or two or three small masses run together, of the same yellow sarcode stuck against one side, the remainder of the chamber being empty. No definite arrangement, and no approach to structure, was observed in the sarcode, and no differentiation, with the exception of round bright-yellow oil-globules, very much like those found in some of the Radiolarians, which are scattered apparently irregularly in the sarcode. We never have been able to detect the least trace of pseudopodia in any of the large number of *Globigerina* which we have examined, nor any extension, in any form, of the sarcode beyond the shell.

Major Owen (*op. cit.*) has referred the *Globigerina* with spines to a distinct species, under the name of *G. hirsuta*. I am inclined rather to believe that all *Globigerina* are, to a greater or less degree, spiny, when the shell has attained its full development. In specimens taken with the tow-net the spines are very usually absent; but that is probably on account of their extreme tenuity; they are broken off by the slightest touch. In fresh examples from the surface the dots indicating the origin of the lost spines may almost always be made out with a high power. There never are spines on the *Globigerina* from the bottom, even in the shallowest water. Two or three very marked varieties of *Globigerina* occur; but I certainly do not think that the characters of any of them can be regarded as of specific value.

There is still a good deal of obscurity about the nature of *Orbulina universa*, an organism which occurs in some places in large proportion in the *Globigerina*-ooze. The shell of *Orbulina* (Pl. II.) is spherical, usually about .5 millimetre in diameter, but it is found of all smaller sizes. The texture of the mature shell resembles closely that of *Globigerina*, but it differs in some important particulars. The pores are markedly of two different sizes, the larger about four times the area of the smaller. The larger pores are the less numerous; they are scattered over the surface of the shell without any appearance of regularity; the smaller pores occupy the spaces between the larger. The crests between the pores are much less regular in *Orbulina* than they are in *Globigerina*; and the spines, which are of great length and extreme tenuity, seem rather to arise abruptly from the top of scattered papillæ than to mark the intersections of the crests.

some cases to about twenty per cent.) of fine granular matter, which fills the shells and the interstices between them, and forms a kind of matrix or cement. This granular substance is, like the shells, calcareous, disappearing in weak acid to a small insoluble residue; with a low microscopic power it appears amorphous, and it is likely to be regarded, at first sight, as a paste made up of the ultimate calcareous particles of the disintegrated shells; but under a higher power it is found to consist almost entirely of "coccoliths" and "rhabdoliths." I need scarcely enter here into a detailed description of these singular bodies, which have already been carefully studied by Huxley, Sorby, Gümbel, Haeckel, Carter, Oscar Schmidt, Wallich, and others. I need only state that I believe our observations have placed it beyond a doubt that the "coccoliths" are the separated elements of a peculiar calcareous armature which covers certain spherical bodies (the "coccospheres" of Dr. Wallich). The rhabdoliths are the like elements of the armature of extremely beautiful little bodies, of which two forms are represented in Pl. III. figs. 3 & 4, which have been first observed by Mr. Murray and naturally called by him "rhabdospheres." Coccospheres and rhabdospheres live abundantly on the surface, especially in warmer seas. If a bucket of water be allowed to stand over night with a few pieces of thread in it, on examining the threads carefully many examples may usually be found attached to them; but Mr. Murray has found an unfailing supply of all forms in the stomachs of *Salpa*.

What these coccospheres and rhabdospheres are, we are not yet in a position to say with certainty; but our strong impression is that they are either *Algæ* of a peculiar form, or the reproductive gemmules or the sporangia of some minute organism, probably an *Alga*; in which latter case the coccoliths and rhabdoliths might be regarded as representing in position and function the "amphidisci" on the surface of the gemmules of *Spongilla*, or the spiny facets on the zygospores of many of the *Desmidiæ*. There are many forms of coccoliths and rhabdoliths, and many of these are so distinct that they evidently indicate different species. Mr. Murray believes, however, that only one form is met with on one sphere; and that, in order to produce the numerous forms figured by Haeckel and Oscar Schmidt, all of which, and many additional varieties, he has observed, the spheres must vary in age and development, or in kind. Their constant presence in the surface-net, in surface-water drawn in a bucket, and in the stomachs of surface-animals, sufficiently proves that, like the ooze-forming *Foraminifera*, the coccoliths and rhabdoliths, which enter so largely into the composition of the recent deep-sea calcareous formations, live on the surface and at intermediate depths, and sink to the bottom after death. Coccospheres and rhabdospheres have a very wide, but not an unlimited, distribution. From the Cape of Good Hope they rapidly decreased in number on the surface and at the bottom, as we progressed southwards. The proportion of their remains in the *Globigerina*-ooze near the Crozets and Prince Edward Island was com-

paratively small; and to this circumstance the extreme clearness and the unusual appearance of being composed of *Globigerina* alone was probably mainly due. We found the same kind of ooze, nearly free from coccoliths and rhabdoliths, in what may be considered about a corresponding latitude in the north, to the west of Farøe.

Before leaving the subject of the modern Chalk, it may be convenient to pass on to stations 158, 159, and 160, on March 7th, 10th, and 13th, on our return voyage from the ice. The first two of these, at depths of 1800 and 2150 fathoms respectively, are marked on the chart "*Globigerina*-ooze;" and it will be observed that these soundings nearly correspond in latitude with the like belt which we crossed going southwards; the third sounding, at a depth of 2600 fathoms, is marked "red clay."

According to our present experience, the deposit of "*Globigerina*-ooze" is limited to water of a certain depth, the extreme limit of the pure characteristic formation being placed at a depth of somewhere about 2250 fathoms. Crossing from these shallower regions occupied by the ooze into deeper soundings, we find universally that the calcareous formation gradually passes into, and is finally replaced by, an extremely fine pure clay, which occupies, speaking generally, all depths below 2500 fathoms, and consists, almost entirely, of a silicate of the red oxide of iron and alumina. The transition is very slow, and extends over several hundred fathoms of increasing depth; the shells gradually lose their sharpness of outline and assume a kind of "rotten" look and a brownish colour, and become more and more mixed with a fine amorphous red-brown powder, which increases steadily in proportion until the lime has almost entirely disappeared. This brown matter is in the finest possible state of subdivision, so fine that when, after sifting it to separate any organisms it might contain, we put it into jars to settle, it remained for days in suspension, giving the water very much the appearance and colour of chocolate.

In indicating the nature of the bottom on the charts, we came from experience, and without any theoretical consideration, to use three terms for soundings in deep water. Two of these, Gl. oz. and r. cl., were very definite, and indicated strongly marked formations, with apparently but few characters in common; but we frequently got soundings which we could not exactly call either "*Globigerina*-ooze" or "red clay;" and before we were fully aware of the nature of these we were in the habit of indicating them as "grey ooze" (gr. oz.). We now recognize the "grey ooze" as an intermediate stage between the *Globigerina*-ooze and the red clay; we find that, on one side as it were of an ideal line, the red clay contains more and more of the material of the calcareous ooze, while, on the other, the ooze is mixed with an increasing proportion of "red clay."

Although we have met with the same phenomenon so frequently, that we were at length able to predict the nature of the bottom from the

... passing still contains a considerable amount of lime.

The depth goes on increasing, to a distance of 11½ miles, when it reaches 3150 fathoms; there the clay is found and contains scarcely a trace of lime. From this grey gradually rises, and, with decreasing depth, the grey arenaceous composition of the ooze returns. Three soundings and 1950 fathoms on the "Dolphin Rise," gave him examples of the *Globigerina* formation. Passing from the Atlantic into the western trough, with depths of 4200 fathoms, the red clay returns in all its purity: and our ship, 420 fathoms, before reaching Sombrero, restored them with its peculiar associated fauna.

This section shows also the wide extension and the importance of the red-clay formation. The total distance from Sombrero is about 2700 miles. Proceeding from east to west:

About 80 miles of volcanic mud and sand

„ 350 „ „ „ *Globigerina*-ooze,”

„ 1050 „ „ „ red clay,”

„ 330 „ „ „ *Globigerina*-ooze,”

„ 850 „ „ „ red clay,”

„ 40 „ „ „ *Globigerina*-ooze,”

making a total of 1900 miles of red clay to 720 miles of *Globigerina* ooze. The following Table, taken from the chart, gives a general distribution of the two formations with respect to distance. It of course be taken as exact: the distances are

about 2700 fathoms. The general concurrence of so many observations would go far to prove, what seems now to stand, indeed, in the position of an ascertained fact, that wherever the depth increases from about 2200 to 2600 fathoms, the modern Chalk formation of the Atlantic and of other oceans passes into a clay.

The nature and origin of this vast deposit of clay is a question of the very greatest interest ; and although I think there can be no doubt that it is in the main *solved*, yet some matters of detail are still involved in

difficulty. My first impression was, that it might be the most minutely divided material, the ultimate sediment, produced by the disintegration of the land, by rivers and by the action of the sea on exposed coasts, and held in suspension and distributed by ocean currents, and only making itself manifest in places unoccupied by the *Globigerina*-ooze. Several circumstances seemed, however, to negative this mode of origin. The formation seemed too uniform; whenever we met with it, it had the same character, and it only varied in composition in containing less or more carbonate of lime.

Again, we were gradually becoming more and more convinced that all the important elements of the *Globigerina*-ooze lived on the surface; and it seemed evident that, so long as the conditions on the surface remained the same, no alteration of contour at the bottom could possibly prevent its accumulation; and the surface conditions in the Mid-Atlantic were very uniform, a moderate current of a very equal temperature passing continuously over elevations and depressions, and everywhere yielding to the tow-net the ooze-forming Foraminifera in the same proportion. The Mid-Atlantic swarms with pelagic Mollusca; and, in moderate depths, the shells of these are constantly mixed with the *Globigerina*-ooze, sometimes in number sufficient to make up a considerable portion of its bulk. It is clear that these shells must fall in equal numbers upon the red clay; but scarcely a trace of one of them is ever brought up by the dredge on the red-clay area. It might be possible to explain the absence of shell-secreting animals living on the bottom by the supposition that the nature of the deposit was injurious to them; but then the idea of a current sufficiently strong to sweep them away is negatived by the extreme fineness of the sediment which is being laid down; the absence of surface shells appears to be intelligible only on the supposition that they are in some way removed.

We conclude, therefore, that the "red clay" is not an additional substance introduced from without, and occupying certain depressed regions on account of some law regulating its deposition; but that it is produced by the removal, by some means or other, over these areas, of the carbonate of lime which forms probably about 98 per cent. of the material of the *Globigerina*-ooze. We can trace, indeed, every successive stage in the removal of the carbonate of lime in descending the slope of the ridge or plateau where the *Globigerina*-ooze is forming, to the region of the clay. We find, first, that the shells of pteropods and other surface Mollusca, which are constantly falling on the bottom, are absent, or if a few remain they are brittle and yellow, and evidently decaying rapidly. These shells of Mollusca decompose more easily, and disappear sooner, than the smaller and apparently more delicate shells of Rhizopods. The smaller Foraminifera now give way and are found in lessening proportion to the larger; the coccoliths first lose their thin outer border and then disappear, and the clubs of the rhabdoliths get worn out of shape and are last seen,

under a high power, as minute cylinders scattered over the field. The larger Foraminifera are attacked, and instead of being vividly white and delicately sculptured, they become brown and worn, and finally they break up, each according to its fashion; the chamber-walls of *Globigerina* fall into wedge-shaped pieces which quickly disappear, and a thick rough crust breaks away from the surface of *Orbulina*, leaving a thin inner sphere, at first beautifully transparent, but soon becoming opaque and crumbling away.

In the mean time, the proportion of the amorphous "red clay" to the calcareous elements of all kinds, increases, until the latter disappear, with the exception of a few scattered shells of the larger Foraminifera, which are still found, even in the most characteristic samples of the "red clay."

There seems to be no room left for doubt that the red clay is essentially the insoluble residue, the ash, as it were, of the calcareous organisms which form the *Globigerina*-ooze, after the calcareous matter has been by some means removed. An ordinary mixture of calcareous Foraminifera with the shells of Pteropods, forming a fair sample of "*Globigerina*-ooze" from near St. Thomas, was carefully washed and subjected by Mr. Buchanan to the action of weak acid; and he found that there remained, after the carbonate of lime had been removed, about one per cent. of a reddish mud, consisting of silica, alumina, and the red oxide of iron. This experiment has been frequently repeated with different samples of "*Globigerina*-ooze," and always with the result that a small proportion of a red sediment remains, which possesses all the characters of the "red clay."

In the *Globigerina*-ooze, siliceous bodies, including the spicules of Sponges, the spicules and tests of Radiolarians, and the frustules of Diatoms occur in appreciable proportion; and these also diminish in number, and the more delicate of them disappear in the transition from the calcareous ooze to the "red clay."

I have already alluded to the large quantity of nodules of the peroxide of manganese which were brought up by the trawl from the red-clay area on the 13th of March. Such nodules seem to occur universally in this formation. No manganese can be detected in the *Globigerina*-ooze; but no sooner has the removal of the carbonate of lime commenced than small black grains make their appearance, usually rounded and mammillated on the surface, miniatures, in fact, of the larger nodules which abound in the clay; and, at the same time, any large organic body, such as a shark's tooth, that may happen to be in the ooze is more or less completely replaced by manganese; and any inorganic body, such as a pebble or a piece of pumice, is coated with it, as a fine black mammillated layer. It is not easy to tell what the proportion of manganese in the red clay may be, but it is very considerable. At station 160, on the 13th of March, the trawl brought up nearly a bushel of nodules, from the size of a walnut to that of an orange; but these were probably the result of the sifting of a large quantity of the

clay. The manganese is doubtless, like the iron, set free by the decomposition of the organic bodies and tests. It is known to exist in the ash of some Algae to the amount of 4 per cent.

The interesting question now arises as to the cause and method of the removal of the carbonate of lime from the cretaceous deposit; and on this matter we are not yet in a position to form any definite conclusion.

One possible explanation is sufficiently obvious. All sea-water contains a certain proportion of free carbonic acid, and Mr. Buchanan believes that he finds it rather in excess in bottom-water from great depths. At all events, the quantity present is sufficient to convert into a soluble compound, and thus remove a considerable amount of carbonate of lime. If the balance of supply be very delicately adjusted, it is just conceivable that the lime in the shells, in its fine state of subdivision, having been attacked by the sea-water from the moment of the death of the animal, may be entirely dissolved during its retarded passage through the half mile or so of water of increasing density. A great deal of the bottom-water in these deep troughs has been last at the surface, in the form of circumpolar freshwater ice; and though fully charged with carbonic acid, it is possible that it may be comparatively free from carbonate of lime, and that its solvent power may thus be greater.

The red clay or, more probably, the circumstances which lead to its deposition seem on the whole unfavourable to the development of animal life. Where its special characters are most marked, no animals which require much carbonate of lime for the development of their tissues or of their habitations appear to exist. Our growing experience is, that although animal life is possible at all depths, after a certain depth, say 1500 fathoms, its abundance diminishes. This would seem to indicate that the extreme conditions of vast depths are not favourable to its development; and one might well imagine that the number of shell-building animals might decrease, until the supply of lime was so far reduced as to make it difficult for them to hold their own against the solvent power of the water of the sea—just as in many districts where there is little lime, the shells of land and freshwater mollusks are light and thin, and the animals themselves are stunted and scarce.

It seems, however, that neither the extreme depth at which the red clay is found, nor the conditions under which it is separated and laid down, are sufficient entirely to negative the existence of living animals, even of the higher invertebrate orders. In several of the hauls, we brought up Holothurids of considerable size, with the calcareous neck-rings very rudimentary, and either no calcareous bodies in the test, or a mere trace of such. Nearly every haul gave us delicate branching Bryozoa, with the zooëcium almost membranous. One fortunate cast, about 150 miles from Sombrero, brought up, from a depth of 2975 fathoms, very well-marked red mud, which did not effervesce with hydrochloric acid. Entangled in the dredge, and imbedded in the mud, were many of

the tubes of a tube-building annelid, several of them 3 to 4 inches long, and containing the worm, a species of *Myriochele*, still living. The worm-tubes, like all the tests of Foraminifera from the same dredging, were made up of particles of the red clay alone.

It seems evident, from the observations here recorded, that *clay*, which we have hitherto looked upon as essentially the product of the disintegration of older rocks, under certain circumstances, may be an organic formation like chalk; that, as a matter of fact, an area on the surface of the globe, which we have shown to be of vast extent, although we are still far from having ascertained its limits, is being covered by such a deposit at the present day.

It is impossible to avoid associating such a formation with the fine, smooth, homogeneous clays and schists, poor in fossils, but showing worm-tubes and tracks, and bunches of doubtful branching things, such as *Oldhamia*, siliceous sponges, and thin-shelled peculiar shrimps. Such formations, more or less metamorphosed, are very familiar, especially to the student of palæozoic geology, and they often attain a vast thickness. One is inclined, from this great resemblance between them in composition and in the general character of the included fauna, to suspect that these may be organic formations, like the modern red clay of the Atlantic and Southern Sea, accumulations of the insoluble ashes of shelled creatures.

The dredging in the red clay on the 13th of March was unusually rich. The bag contained examples, those with calcareous shells rather stunted, of most of the characteristic deep-water groups of the Southern Sea, including *Umbellularia*, *Euplectella*, *Pterocrinus*, *Biringa*, *Ophioglypha*, *Pourtalesia*, and one or two Mollusca. This is, however, very rarely the case. Generally the "red clay" is barren, or contains only a very small number of forms.

On the 11th of February, lat. 60° 52' S., long. 80° 20' E., and March 3, lat. 53° 55' S., long. 108° 35' E., the sounding-instrument came up filled with a very fine cream-coloured paste, which scarcely effervesced with acid, and dried into a very light impalpable white powder. This, when examined under the microscope, was found to consist almost entirely of the frustules of Diatoms, some of them wonderfully perfect in all the details of their ornament, and many of them broken up. The species of diatoms entering into this deposit have not yet been worked up, but they appear to be referable chiefly to the genera *Fragillaria*, *Coscinodiscus*, *Chaetoceros*, *Asteromphalus*, and *Dictyocha*, with fragments of the separated rods of a singular siliceous organism, with which we were unacquainted, and which made up a large proportion of the finer matter of this deposit. Mixed with the Diatoms there were a few small *Globigerina*, some of the tests and spicules of Radiolarians, and some sand particles; but these foreign bodies were in too small proportion to affect the formation as consisting practically of diatoms alone. On the 4th of February, in lat. 52° 20' S., long. 71° 36' E., a little to the north of the

Heard Islands, the tow net, dragging a few fathoms below the surface, came up nearly filled with a pale yellow gelatinous mass. This was found to consist entirely of Diatoms of the same species as that found at the bottom. By far the most abundant was the little bundle of siliceous rods (Pl. III. fig. 5) fastened together loosely at one end, separating from one another at the other end, and the whole bundle loosely twisted into a spindle. The rods are hollow, and contain the characteristic endochrome of the *Diatomaceæ*. Like the "*Globigerina-ooze*," then, which it succeeds to the southward in a band apparently of no great width, the materials of this siliceous deposit are derived entirely from the surface and intermediate depths. It is somewhat singular that Diatoms did not appear to be in such large numbers on the surface over the Diatom-ooze as they were a little further north. This may perhaps be accounted for by our not having struck their belt of depth with the tow-net; or it is possible that when we found it, on the 11th of February, the bottom deposit was really shifted a little to the south by the warm current, the excessively fine flocculent *débris* of the Diatoms taking a certain time to sink. The belt of Diatom-ooze is certainly a little further to the southward in long. 80° E. in the path of the reflux of the Agulhas current, than in long. 108° E.

All along the edge of the ice pack—everywhere in fact to the south of the two stations, that of the 11th of February, on our southward voyage, and that of the 3rd of March, on our return, we brought up fine sand and greyish mud, with small pebbles of quartz and felspar, and small fragments of mica-slate, chlorite-slate, clay-slate, gneiss, and granite. This deposit, I have no doubt, was derived from the surface like the others, but, in this case, by the melting of icebergs and the precipitation of foreign matter contained in the ice.

We never saw any trace of gravel or sand, or any material necessarily derived from land, on an iceberg. Several showed vertical or irregular fissures filled with discoloured ice or snow; but, when looked at closely, the discoloration proved usually to be very slight, and the effect, at a distance, was usually due to the foreign material which filled the fissure reflecting light less perfectly than the general surface of the berg. I conceive that the upper part of one of these great tabular southern icebergs, including by far the greater part of its bulk, and culminating in the portion exposed above the surface of the sea, was formed by the piling up of successive layers of snow throughout the period, amounting perhaps to several centuries, during which the ice-cap was slowly forcing itself over the low land and out to sea, over a long extent of gentle slope, until it reached a depth considerably above 200 fathoms, when the lower specific weight of the ice caused an upward strain, which at length overcame the cohesion of the mass, and portions were rent off and floated away. If this be the true history of the formation of these icebergs, the absence of all land *débris* in the portion exposed above the surface of the

the tubes of a tube-building annelid, several of them 3 to 4 inches long, and containing the worm, a species of *Myriochele*, still living. The worm-tubes, like all the tests of Foraminifera from the same dredging, were made up of particles of the red clay alone.

It seems evident, from the observations here recorded, that clay, which we have hitherto looked upon as essentially the product of the disintegration of older rocks, under certain circumstances, may be an organic formation like chalk; that, as a matter of fact, an area on the surface of the globe, which we have shown to be of vast extent, although we are still far from having ascertained its limits, is being covered by such a deposit at the present day.

It is impossible to avoid associating such a formation with the fine, smooth, homogeneous clays and schists, poor in fossils, but showing worm-tubes and tracks, and bunches of doubtful branching things, such as *Oldhamia*, siliceous sponges, and thin-shelled peculiar shrimps. Such formations, more or less metamorphosed, are very familiar, especially to the student of palæozoic geology, and they often attain a vast thickness. One is inclined, from this great resemblance between them in composition and in the general character of the included fauna, to suspect that these may be organic formations, like the modern red clay of the Atlantic and Southern Sea, accumulations of the insoluble ashes of shelled creatures.

The dredging in the red clay on the 13th of March was unusually rich. The bag contained examples, those with calcareous shells rather stunted, of most of the characteristic deep-water groups of the Southern Sea, including *Umbellularia*, *Euplectella*, *Pterocrinus*, *Brisinga*, *Ophioglypha*, *Purtalesia*, and one or two Mollusca. This is, however, very rarely the case. Generally the "red clay" is barren, or contains only a very small number of forms.

On the 11th of February, lat. 60° 52' S., long. 80° 20' E., and March 3, lat. 53° 55' S., long. 108° 35' E., the sounding-instrument came up filled with a very fine cream-coloured paste, which scarcely effervesced with acid, and dried into a very light impalpable white powder. This, when examined under the microscope, was found to consist almost entirely of the frustules of Diatoms, some of them wonderfully perfect in all the details of their ornament, and many of them broken up. The species of diatoms entering into this deposit have not yet been worked up, but they appear to be referable chiefly to the genera *Fragillaria*, *Coccinodiscus*, *Chatoceros*, *Asteromphalus*, and *Dictyocha*, with fragments of the separated rods of a singular siliceous organism, with which we were unacquainted, and which made up a large proportion of the finer matter of this deposit. Mixed with the Diatoms there were a few small *Globigerinae*, some of the tests and spicules of Radiolarians, and some sand particles; but these foreign bodies were in too small proportion to affect the formation as consisting practically of diatoms alone. On the 4th of February, in lat. 52° 20' S., long. 71° 36' E., a little to the north of the

of this siliceous deposit are derived from intermediate depths. It is somewhat singular to find them in such large numbers on the surface where they were a little further north. This may be due to not having struck their belt of depth when we found it, on the 11th of February, but it really shifted a little to the south by the fine flocculent *débris* of the Diatoms taken from the belt of Diatom-ooze is certainly a little further south. long. 80° E. in the path of the reflux of the Gulf Stream. long. 108° E.

All along the edge of the ice pack—between the two stations, that of the 11th of February, and that of the 3rd of March, we found fine sand and greyish mud, with small pebbles and small fragments of mica-slate, chlorite, and granite. This deposit, I have no doubt, is of the same origin as the others, but, in this case, by the precipitation of foreign matter contained in the water.

We never saw any trace of gravel or sand derived from land, on an iceberg. Several icebergs were fissured with discoloured ice or snow, and the discoloration proved usually to be very recent. At a short distance, was usually due to the foreign matter in the water reflecting light less perfectly than the green ice. We can conceive that the upper part of one of the icebergs, including by far the greater part of the mass, is of the same origin.

we hope to retain undisturbed occupation for some generations to come, an account of the present position of the Society in respect of our more important possessions, foundations, and functions, and our relations to the Government, would not only be generally acceptable, but might even be required of me by that large and increasing class of Fellows who live far from our doors. This class now numbers as nearly as possible one half of the Society, few of whom can be even occasional attendants at our Meetings; and if to this class of absentees be added the large number of residents within the metropolitan district whose avocations prevent their attending, it will not surprise you to hear that (as I have ascertained by careful inquiry) a very large proportion of our fellow Members know little of the Society's proceedings beyond what appears in our periodical publications, nor of our collections, nor of the tenure under which we occupy our apartments under the Crown—and that many have never heard of the funds we administer, whether our own or those voted by Parliament in aid of scientific research, nor of the fund for relief of the necessitous, nor of the gratuitous services rendered by the Society to various departments of the Government.

Unlike the great Academies of the continent, the Royal Society has never published an Almanack or Annuaire containing information upon its privileges, duties, constitution, and management. Particulars on these points are for the most part now accessible to the Fellows only by direct inquiry, or through the Council Minutes; and these, to non-resident Fellows, are practically inaccessible. In my own case, though I have long been a resident Fellow and had the honour of serving on your Councils for not a few years, it was not until I was placed in the position I now hold that I became aware of the number and magnitude of the Society's duties, or of the responsibility these impose on your officers.

It is upwards of a quarter of a century since an account of the foundations that then existed and the work the Society then carried on was published in Weld's valuable, but too diffuse, '*History of the Royal Society.*' These have all been greatly modified or extended since that period; and many others have been added to them; so that the time has now arrived when a statement of the large funds applicable to scientific research which the Society distributes, the conditions under which these are to be applied for, and other particulars, might with advantage be published in a summary form and distributed to the Fellows annually.

*Finance.*—After the financial statement made by the Auditors, you will, I am sure conclude that there is no cause for apprehension in respect of the Society's funds or income; and when to this I add that the expenses of removal from the old House, including new furniture, amount to £1300, and that the volume of Transactions for the present year will contain eighty-six Plates, the largest number hitherto executed at the

Society's cost within the same period, you will also conclude that there is no want of means for providing illustrations to papers communicated to us for publication.

The landed property of the Society, as stated in the printed balance-sheet now before you, consists of an estate at Acton, in the neighbourhood of London, and an estate at Mablethorpe, Lincolnshire; each yielding a good rental. The Acton estate, at present on lease to an agricultural tenant, is planned to be let as building land, for which it is favourably situate, and will thus become increasingly valuable.

The subject of the tenure under which the Society holds the apartments we now occupy was brought up on a question of Insurance. That question has been satisfactorily settled by reference to the Treasury; but it may still be worth while briefly to state the facts which the Council considered as furnishing valid grounds for appealing against the requirement to insure, and for at the same time requesting an assurance that the permanence of our tenure is in no way weakened by our removal to this building. These are:—that when the apartments in Somerset House were originally assigned to the Society by command of George III., they were granted “during the pleasure of the Crown without payment of rent or any other pecuniary consideration whatever;” that the Society was not required to insure either in Somerset House or old Burlington House; that when the Society removed at the request of the Government from Somerset House, and accepted temporary accommodation in Burlington House, it was under the written assurance of the Secretary of the Treasury, addressed to the President of the Society, that the claims of the Society to “permanent accommodation should not be thereby in any respect weakened;” that in the debate on the estimates in 1857, the Secretary of the Treasury stated, in his place in Parliament, that “the Society could not be turned out of Somerset House without its own consent,” and that “it was entitled to rooms by Royal grant.”

To this appeal the Lords Commissioners returned a satisfactory answer; and their letter, dated October 27th last, assures us “that there is no intention on the part of the Treasury to alter the terms on which the Royal Society holds its appointments under the Crown; the conditions of the Society's tenure will therefore be the same as those on which it occupied rooms in Somerset House, and was subsequently transferred to Burlington House.”

While feeling it my duty to lay these details before you, I must accompany them with the assurance that nothing has occurred during this correspondence to disturb the unbroken harmony that has existed between Her Majesty's Government and the Royal Society ever since our occupation of apartments under favour of the Crown.

On every occasion of change of quarters the Society has received abundant proofs of the regard shown by the Government for its position,

requirements, and continued prosperity; and there is, I am sure, every disposition on the part of the Government to recognize the fact that the privileges conferred on the Society are fully reciprocated by the multifarious aid and advice furnished by your Council in matters of the greatest importance to the well-being of the State.

The practice of electing Fellows of the so-called privileged class whose qualifications were limited to accident of lineage or political status, has been viewed with grave dissatisfaction by many, ever since the election of ordinary Fellows was limited to fifteen. The Council has in consequence felt it to be its duty to give most careful attention to the subject, which it referred to a Committee, whose report has been adopted and embodied in a bye-law.

The privileged class consisted, as you are aware, of certain Royal personages, Peers of the Realm and Privy Councillors (Statutes, Sect. IV. cap. 1); and they were balloted for at any meeting of the Society, after a week's notice given on the part of any Fellow, without a suspended certificate, or other form whatever.

The Committee reported that it was desirable to retain the power of electing, as a "privileged class," persons who, while precluded by public duties or otherwise from meeting the scientific requirements customary in the case of ordinary Fellows, possessed the power and had shown the wish to forward the ends of the Society, and recommended that the class should be limited to the Princes of the Blood Royal, and members of Her Majesty's Privy Council. And with regard to the method of election, they recommended that a Prince of the Blood Royal might be publicly proposed at any ordinary meeting, and balloted for at the next; that, with regard to a member of Her Majesty's Privy Council, he might be proposed at any ordinary meeting by means of a certificate prepared in accordance with Chap. I. Sect. 3 of the Statutes, membership of the Privy Council being the only qualification stated—the certificate being, with the Society's permission, suspended in the meeting-room till the day of election, which should fall on the third ordinary meeting after suspension.

Having regard to the eminent services to the State which have been rendered by Privy Councillors, and to the fact that all Peers who do render such services are habitually enrolled on the list of Privy Councillors, it was believed by the Council that the effect of thus limiting the privileged class would be that the doors of the Society would remain open to all such Peers as desire and deserve admission, but who have not the ordinary qualifications for fellowship; while all such Peers as might appear with claims which compete with those of ordinary candidates would prefer owing the fellowship to their qualifications rather than to their birth.

The Council hopes that by this means the so-called privileged class

will be reinforced, and that statesmen who may have considered themselves inelegible through want of purely scientific qualifications, or who have hesitated to offer themselves from the fear of interfering with the scientific claims of others, will in future come forward and recruit our ranks.

A passing notice of the manner of proposing candidates for the ordinary class of fellowship may not be out of place. Theoretically this is done by a Fellow who is supposed to be a friend of the candidate, is versed in the science on which his claims are founded, and is satisfied of his fitness in all respects for fellowship. It is most desirable that the Fellow who proposes a candidate should take upon himself the whole duty and responsibility of preparing the certificate, should sign it first, and himself procure the signatures of other Fellows in whose judgment of the candidate's qualifications the Council and the Society may place implicit confidence. It is unsatisfactory to see attached to a candidate's certificate an ill-considered list of signatures, whether given from personal or from general knowledge; and the happily rare practice of soliciting signatures and support, directly or indirectly, by the candidate himself, cannot be too strongly deprecated. For obvious reasons the President, Officers, and other Members of Council have hitherto during their periods of office abstained from proposing a candidate of the ordinary class or from signing his certificate, but have not withdrawn their signatures from certificates sent in before they took office. The Council and Officers will probably not feel the same objection to signing the certificates of candidates of the privileged class, as these will not be selected for ballot by the Council, but will be elected by the Society at large at their ordinary meetings.

In carrying on the business of the Society the Council is much indebted to Committees appointed annually for special purposes, or to whom an occasional question is referred. The annual appointments include the Government-Grant, the Library, the Soirée, and the Acton-Estate Committees. The temporary Committees of the past year have been the Circumnavigation, the Transit-of-Venus-Expeditions, the Arctic, the House, the Brixham-Cave, the Privileged-Classes, and the Davy-Medal Committee. Besides these there are two permanent Committees, the Meteorological and the Scientific-Relief, to which fresh Members are appointed as vacancies occur. From these designations it will be understood that some of the Committees have been occupied with questions connected with the Government service, while others have devoted themselves exclusively to the business of the Society.

I shall now mention such of the labours of these Committees as seem to be most worthy of your attention.

The *Meteorological Committee of the Board of Trade*, as it ought to be called, discharges in all respects the most arduous and responsible duties of any, controlling as it does the whole machinery of the British

Government for the making, registering, and publishing of especially oceanic meteorological phenomena throughout the globe.

The primary purpose for which this and all similar offices were established, was the acceleration of ocean passages for vessels by an accurate investigation of the prevalent winds and currents. In other words, their great object is to aid the seaman in what Captain Basil Hall called "one of the chief points of his duty"—namely, "to know when to find a fair wind, and where to fall in with a favourable current." The first impulse to the formation of an Office for this purpose was given by the late General Sir J. Burgoyne, who in 1852 started the idea of land observations to be carried out by the Corps of Royal Engineers.

Shortly afterwards our Government corresponded with the United-States Government on the subject of cooperating in a scheme for land observations, which was followed by a suggestion on the part of America that the operations should be extended to the sea.

The correspondence was referred to the Royal Society, which warmly approved the scheme of sea observations, but saw many difficulties in carrying out that for the land. The Brussels Conference followed in 1853, when representatives of most of the maritime nations assembled and adopted a uniform plan of action. Soon after this, Lord Cardwell, then President of the Board of Trade, established the Meteorological Department of that office, and placed the late Admiral FitzRoy at the head of it—the Royal Society, at the request of the Government, supplying copious and complete instructions for his guidance, which were drawn up mainly by Sir Edward Sabine. Admiral FitzRoy's zeal and his great labours are known to all; he worked out the system of verifying and lending instruments, planning surveys, registering observations, publishing results; and, lastly, himself originated the plan of predicting the weather, and establishing storm-signals at the sea-ports along the coast.

On Admiral FitzRoy's death in 1865 the Royal Society was again consulted as to the position and prospects of the Office. Its Report, which did not differ materially from that of 1855, was in 1866 referred to a Committee, composed of a representative of the Board of Trade, of the Admiralty, and of the Royal Society. This Committee supported the previously expressed views of the Society, and suggested the placing of the Office under efficient scientific superintendence; upon which the Society, in the same year, was requested by the Government to undertake the superintendence of what had been the Meteorological Department of the Board of Trade. To this request the Council of the Society so far acceded as to nominate a Committee of eight Fellows (subsequently increased to ten) to undertake the entire and almost absolute control of the Office; and a Parliamentary grant of £10,000 per annum was provided to maintain it.

This is in brief the history of the connexion between the Royal Society and the Meteorological Office on the one hand, and between the Office and

at on the other. It is a very anomalous position, and has been misunderstood. It has led to the misconception on the part of some that the Society controlled the Office, and by others that the Board of Trade controlled it, and by more that the £10,000 is made to and in support of the Royal Society, for its objects, whereas the grant is paid direct to the Director of the Office as soon as voted. The Society's action is confined to the Committee, which superintends the Office, while the Board of Trade, by reporting to the Committee the details of their operations, exercise a general control. The labours of the Committee are entirely unremunerated, and no part of the £10,000 is touched by them or by the

There is no parallel to such an organization as this in any other part of the Government. It has its advantage in securing to the Office a freedom from that disturbing element in the public offices, the Ministers, who are chosen partly on political grounds and change with the Government, and its disadvantage in wanting the support of direct authority and prestige. Hitherto, owing to the care of the Committee (which meets almost weekly, to the zeal and efficiency of the Committee (the Secretary to the Committee) and of the Marine Committee, it has worked well. Into its working it is not my purpose to enter; its efficiency and value are fully acknowledged by the Government, and the best practical proof of this can be cited than the general

stratification of an oceanic area of about 15 million square miles and with an average depth of 15,000 feet. Nor are the results of the Pacific Survey less important. Some of these were laid before you at our meeting of the 28th inst. in Prof. Wyville Thomson's "Preliminary Notes on the Nature of the Sea-Bottom in the South Sea," which reveal the existence of hitherto unsuspected processes of aqueous metamorphism at great depths in the ocean, and throw an entirely new light upon the geological problem of the origin of "azoic" clays and schists.

Valuable papers on new and little-known marine animals have been contributed to our Transactions and Proceedings by Mr. Willemoes-Suhm, Mr. Moseley, and other members of the Civilian Scientific Staff of the 'Challenger;' and a Number of the Journal of the Linnean Society is devoted to the Botanical observations and collections made by Mr. Moseley during the course of the voyage.

*Transit-of-Venus Committee.*—Upon the representation of your Council, Her Majesty's Government has attached naturalists to two of the astronomical expeditions sent out from this country to observe the approaching transit of Venus. The stations selected were the two most inaccessible to ordinary cruisers, and at the same time most interesting in regard to their natural productions—namely, the island of Rodriguez in the Mauritius group, and Kerguelen's Land in the South Indian Ocean.

The objects and importance of these appointments were laid before the Government in the following statement:—

"It is an unexplained fact in the physical history of our globe, that all known oceanic archipelagos distant from the great continents, with the sole exceptions of the Seychelles and of a solitary islet of the Mascarene group (which islet is Rodriguez), are of volcanic origin. According to the meagre accounts hitherto published, Rodriguez consists of granite overlaid with limestone and other recent rocks, in the caves of which have been found the remains of recently extinct birds of a very singular structure. These facts, taken together with what is known of the Natural History of the volcanic islets of Mauritius and Bourbon to the west of Rodriguez and of the granitic archipelago of the Seychelles to the north of it, render an investigation of its natural products a matter of exceptional scientific interest, which, if properly carried out, cannot fail to be productive of most important results.

"As regards Kerguelen's Land, this large island (100 by 50 miles) was last visited in 1840, by the Antarctic Expedition under Sir James Ross, in midwinter only, when it was found to contain a scanty flora of flowering plants, some of which belong to entirely new types, and an extraordinary profusion of marine animals and plants of the greatest interest, many of them being representatives of north-temperate and Arctic forms of life.

"H.M.S. 'Challenger' will no doubt visit Kerguelen's Land, and

collect largely ; but it is evident that many years would be required to obtain even a fair representation of its marine products ; and though we are not prepared to say that the scientific objects to be obtained by a naturalist's visit to Kerguelen's Land are of equal importance to those which Rodriguez will yield, we cannot but regard it as in every respect most desirable that the rare opportunity of sending a collector to Kerguelen's Land should not be lost."

I may further state as a matter of great scientific interest, that Rodriguez contains the remains of a gigantic species of land-tortoise allied to those still surviving in some other islands of the Mauritian group, and that the nearest allies of these are the gigantic tortoises of the Galapagos Islands in the opposite hemisphere of the globe, as one of our Fellows, Dr. Gunther, has shown in a paper read last Session to the Society. Very valuable collections of these fossils have been made by Mr. Newton, the Colonial Secretary of Mauritius, during a brief stay which he was enabled to make in Rodriguez ; but the materials are far from sufficient for obtaining all the information we want.

In accordance with your Council's recommendation, the Treasury sanctioned the appointment of four naturalists—three to Rodriguez, and one to Kerguelen's Land. Those sent out to Rodriguez are:—Mr. I. B. Balfour, son of Prof. Balfour, of Edinburgh, F.R.S., who, besides being educated as a botanist, has worked as a field geologist in the Geological Survey of Scotland ; he is charged with the duties of botanist and geologist ; Mr. George Gulliver, son of one of our Fellows and a pupil of Professor Rolleston, in Oxford, who goes out as naturalist ; and Mr. H. H. Slater, who has had great experience as a cave-explorer, and who will devote his attention especially to the collection of fossils.

The Kerguelen's-Land duties are undertaken by the Rev. A. E. Eaton, M.A., a gentleman most favourably known as an entomologist, and who had made very important collections in Spitzbergen, which he visited for the purpose of studying its fauna and flora. These gentlemen had, by the last accounts, all proceeded to their destinations.

*Committee of Papers.*—The strength of the Society being represented by its publications, the Committee of Papers is the one whose functions are unquestionably the highest and most onerous, as they are the most closely scrutinized by the Fellows and the public.

Every member of the Council is included in this Committee, which meets after almost every Council-meeting ; and no part of its duties is at present performed by a subcommittee. It appears to me to be very doubtful whether this arrangement, even if the best, can last, owing to the greatly increased number of papers now communicated and their augmenting bulk, and to the value of their contents being less easily estimated as the subjects of scientific research become more specialized. As it is, in the majority of cases but few of the members present can

judge of the merits of many of the papers ; and it is not easy after a protracted Council-meeting, and one occupied with promiscuous business, to fix the attention of a large Committee upon subjects with which but few members present may be familiar. It is true that the Committee is aided in all cases by the written opinions of careful and impartial referees, and by the special attainments of our Secretaries, and that it is most desirable that the sometimes divergent opinions of these should be weighed by others as well as by experts in the subjects of the papers. But for all this a Committee of the whole Council is not necessary ; and though I should not be disposed to advocate a return to a system once pursued of resolving the Committee into subcommittees charged with special subjects, I think it possible that some other plan may meet the difficulties of the case and relieve our overburthened Council of much labour. A possible plan for relieving both the Council and the Committee, while securing as careful a scrutiny of the Papers as we now have, would be a division of the labours of the Committee, and an addition of extra members to its number, chosen from among the Fellows, who should continue in office throughout the Session. This, or some plan of the kind, would have the advantage of engaging more of the Fellows than at present in the affairs of the Society ; and I feel sure that so responsible a position as that of Extra Member of the Committee of Papers would be accepted with pride by those Fellows who are most competent to discharge the duties.

It seems convenient to refer here to suggestions that have been made to me as to the expediency of breaking up our Transactions or Proceedings, or both, into sections devoted to Physics and Biology respectively, or even subdividing them still more. This separation has been advocated on the ground that science has become so specialized that no scientific man can grasp all its subdivisions, that the mixed publications are cumbersome and difficult to consult, and that private libraries are now overburthened with the publications of Societies, of each of which a small part would suffice for all their possessors' wants. There is no question that this, if now an evil, will soon become intolerable ; for our publications increase rapidly in number of contributions, and in their bulk. There are, however, so many considerations to be discussed before any system of relief can be adopted, that I confine myself to stating the subject as it has been urged upon me.

The Society's Library now comprehends 36,270 volumes and 10,000 tracts, the most considerable collection of scientific works in the possession of any private body ; and in respect of Transactions and Proceedings of Scientific Academies, Societies, and Institutions, I believe it is unrivalled among public bodies.

A complete Catalogue of the Scientific Books, MSS., and Letters, which I regret to say is unaccompanied by any historical or other information regarding the Library, was printed in 1839. Another Catalogue

purposes, and will be added to until such time as the general  
ready for press.

tion of Oriental MSS. presented by Sir William Jones in  
ded to by his widow in 1797, was largely consulted by  
distinguished foreigners who assembled at the Oriental  
London last September. From conversation with some of  
then, I learnt that the collection contains many documents of  
value and rarity, together with some that are unique; and it  
the consideration of the Council, whether they would not  
ul if transferred to, or deposited in, the India Office or  
oriental Library, where they would be consulted to greater  
here? At present they occupy part of the room devoted

has been £8936 12s., of which £3720 15s. 6d. (the cost of preparation) was defrayed by the Society, and the rest (the cost of printing, paper, and binding) by the Treasury; against which must be set the proceeds of sale, repaid to the Treasury in occasional amounts, the last within the present year, making a total of one thousand pounds.

The number of copies of the Society's Transactions distributed gratuitously to Institutions and Individuals not Fellows of the Society is now 209, and of the Proceedings 325.

*House Committee.*—The great labours of this Committee in connexion with the removal into the apartments we now occupy had not terminated at the beginning of the past Session; and various matters have still to be attended to. That the arrangements the Committee has made have given satisfaction to the Fellows at large has been amply acknowledged. We are, indeed, greatly indebted to them for the knowledge, experience, and time all so freely given in our service, as also to the knowledge of our requirements and the practical views of our Assistant-Secretary, upon whom fell the duty of suggesting the best disposition of the apartments throughout this large and commodious building. Lastly, I would beg your permission to record the services of the eminent architect, Mr. Barry, who has throughout shown the greatest regard to our position and requirements, and but for whose professional ability enlisted in our service we might have found ourselves as ill as we are now well accommodated.

*Funds and Bequests.—The Donation Fund.* In 1828 our former President, Dr. Wollaston, invested £2000 in the Three per Cents for the creation of a Fund, the dividends from which were to be expended liberally "from time to time in promoting experimental researches, or in rewarding those by whom such researches have been made, or in such other manner as shall appear to the President and Council for the time being most conducive to the interests of the Society in particular, or of Science in general." There is no restriction as regards nationality; but Members of Council are excluded from participation during their term of office.

To this Fund many liberal additions were made: Mr. Davies Gilbert gave £1000; Warburton, Hatchett, Guillemard, and Chantrey each contributed 100 guineas. From these gifts, and by accumulations, the Fund in 1849 had increased to £5293. With subsequent contributions, and a bequest of £500 by our eminent Fellow the late Sir Francis Ronalds, the total, as shown by the balance-sheet now in your hands, amounts to £5816 1s. 1d. In addition to the balance-sheet already referred to, a detailed statement of grants from the Donation Fund is, in accordance with a resolution of Council, published with the Report of the Anniversary Meeting.

Sir Francis Ronalds died in 1873; his bequest (reduced by payment of legacy duty to £450) was made, as declared in his Will, in recognition

anges he had derived when Honorary Director of the Observ-  
v. from the sums granted to him out of the Fund to aid  
nstruction of his photographic apparatus for the registration  
Magnetism, Atmospheric Electricity, and other Meteoro-  
mena.

nts made during the past Session, I would especially men-  
Dr. Dohrn in support of the Stazione Zoologica at Naples,  
British naturalists, Mr. Lankester and Mr. Balfour, have  
e a valuable series of observations on marine animals.

others were a grant of £25 to Dr. Carpenter for the purpose  
g an apparatus to illustrate the theory of Oceanic Circula-  
n to temperature, and £50 in aid of the Sub-Wealden Explo-  
ference to this last, I should remark that, in recognition of  
scientific results which have been obtained from the Sub-  
ng (which is now carried to a depth of 1000 feet), and in  
ning further assistance from Her Majesty's Government  
ork, the Council authorized me to lay before the Chancellor  
quer such a statement as I should judge appropriate with the  
ning a grant from the public purse in aid of the boring.

ce of this resolution, I joined the Presidents of the Geo-  
r and of the Institution of Civil Engineers in presenting a  
sh was most favourably received, and was answered by a

tion of education and learning in every part of the world, as circumstances permit," the Trustees having an "absolute and uncontrolled discretion" as to the mode of applying it. The income of the Trust, which is being gradually augmented by the sale of building-lots at Sydney, where Dr. Gilchrist had invested a considerable sum in the purchase of an estate with a view to its ultimate rather than its immediate productiveness, now amounts to about £4000 per annum. The Trustees have created various Scholarships for bringing young men of ability from India and the Colonies to carry on their education in this country; and they have also given assistance to various educational institutions which they considered to have a claim for occasional help from the Fund, such as the Working Men's College in London and the Edinburgh School of Arts; and they have instituted short courses of scientific lectures to working men in London, Manchester, Leeds, and Liverpool.

The Trustees now desire to do something effectual for the *advancement* of learning; and a scheme—subsequently submitted to the Council of the Royal Society—was suggested by Dr. Carpenter, the Secretary of the Trust, as one which seemed to him to be the most effectual for carrying out this object; and it was adopted by the Trustees on his recommendation.

In a letter addressed to myself in June last Dr. Carpenter informed your Council that the Trustees of the Fund had resolved to employ a portion of it in the promotion of scientific research, and empowered him to submit the following liberal proposal to the consideration of your Council: namely, the Trustees propose annually to entertain the question of placing £1000 at the disposal of the Council of the Royal Society to be expended in grants to men of proved ability in scientific research, but who, from their limited pecuniary means, are precluded from prosecuting inquiries of great interest by the necessity of devoting to remunerative work the time they would wish to devote to such inquiries, the Council of the Society to undertake on their part to recommend to the Trustees suitable subjects of inquiry, competent men circumstanced as indicated, and the sum to be assigned in each case. The Trustees desire, further, that the grants should not be regarded as eleemosynary, but rather as Studentships carrying with them scientific distinction, and not as rewards for past work, but as means for work to be done.

Upon this communication (in which you cannot fail to perceive not only an enlightened regard for the interests of science on the part of the Trustees, but, on the part of their Secretary, an accurate perception of the best means of supplying one of the greatest scientific needs), your Council appointed a Committee to report on the proposal. Their labours are already concluded; the proposition has been accepted, but under stipulation for fulfilment of the following conditions by applicants for the grants:—

That the grants should be made for one year only in each case, though subject to renewal.

That the recipients be designated *Gilchrist Students* for the year in which the grants are made.

That no application for grants be received except it has been approved by the President and Council of any one of the six Societies—namely, the Royal, Astronomical, Chemical, Linnean, Geological, and Zoological; and that all applications be submitted to a Committee, consisting of the Presidents of the six Societies together with the Officers of the Royal Society, which Committee shall recommend the applicants to the Gilchrist Trustees.

That a form of application be prepared setting forth the general objects of the Gilchrist Studentships, and the conditions upon which they are conferred.

That each Student furnish, at the end of the year for which the grant is made, a report of his progress and results, signed by himself and countersigned by the President of the Society through which the application was transmitted.

Simple and acceptable as such a scheme appears, it may prove by no means always smooth in the working. It will be easy to find subjects, and candidates too; but the Trustees must not expect in every case a full annual harvest for what they annually sow, or that some of the seed will not be productive of a crop of good intentions rather than good fruits. Putting aside all the temptations to procrastination that prepayment fosters, there is the fact that every subject of scientific research presents a labyrinth in which the investigator may wander further and further from the main gallery, always following some tempting lateral track leading to discovery, but never either reaching the end of it or getting back to that which he set out to follow.

We must, however, hope for the best results from so munificent an endowment of scientific research, and watch with the deepest interest the progress of an experiment, the means for instituting which, after being urgently called for from the Government and our Universities, are now forthcoming from private resources.

*The Wintringham Bequest.*—Hitherto this curious bequest has, so far as the Society is concerned, proved alike profitless and troublesome, as will appear from a few particulars of its history.

Sir Clifton Wintringham, Bart., a Fellow and son of a Fellow of this Society, died at Hammersmith, January 10, 1794, and bequeathed £1200 three-per-cent. Consols (payable twelve months after the decease of his wife) to the Royal Society, subject to the condition that within one month of the payment of the annual dividends in each year the President should fix on the subjects for three essays in Natural Philosophy or Chemistry, and submit them to the Society to be adopted by secret ballot. The subjects were then to be advertised in the papers of London, Paris, and the Hague: the essays were to be sent to the Royal Society within ten months of date of advertisement, each author to deliver ten copies; and

the President and nine Members of Council were to choose the best, and then to have made a silver cup of £30 value, to be presented to the successful essayist on the last Thursday in December. In case of failure the dividends were to be paid to the Treasurer of the Foundling Hospital.

Lady Wintringham died in 1805; but the Royal Society heard nothing of the bequest until 1830, when steps were taken to obtain possession of the fund. The Foundling Hospital put forward their claim; legal proceedings were taken, costs being paid out of accumulated dividends; and in 1842 the Royal Society were put in possession of the £1200 stock. Owing to the essential difficulties of carrying out the conditions of the testator's will, the dividends have ever since been paid to the Foundling Hospital.

The Council, desirous that those difficulties should be overcome, have at different times appointed a Committee to examine the question and suggest if possible a solution; but no satisfactory conclusion has yet been arrived at.

*The Handley Bequest.*—Mr. Edwin Handley, of Old Bracknell, Berks, was a country gentleman, and the possessor of a considerable landed and personal estate in Berkshire and Middlesex. He died in 1843, having bequeathed the bulk of his property, after the decease of his two sisters, to the Royal Society.

The last of these ladies died in 1872, since when certain legal formalities have been complied with, and the claims of the Royal Society to the landed estates under the Mortmain Act have been brought before the Court. In February last the Master of the Rolls decided that "the gifts to the Royal Society, so far as they relate to pure personalty, are good charitable gifts, but otherwise void." The personalty as set forth in the "Bill of Complaint," comprises £6033 7s. 5d. Three-per-Cent. Consols, £1904 17s. 2d. Reduced, and £41 18s. 5d. Bank-of-England Stock.

By the terms of the Will the Society is to preserve the property intact in value, as a Fund Principal, the income of which is to be applied to the rewarding inventions in art, discoveries in science, physical or metaphysical ("which last and highest branch of science," to quote the testator's words, "has been of late most injuriously neglected in this country"), or for the assistance of fit persons in the prosecution of inventions and discoveries. The rewards or assistance are to be granted annually, or after longer periods, to British subjects or foreigners, according to the impartial decision of the President and Council.

*The Dircks Bequest.*—Mr. Henry Dircks, of Liverpool, and latterly of London, who died in 1872, has bequeathed the residue of his property (about £4000), after payment of debts and charges, to the Royal Society, Royal Society of Literature, Chemical Society, and Royal Society of Edinburgh, in equal shares and proportions, in furtherance of their

... Affairs, to the effect that  
of Milan, has bequeathed a portion of his  
-“Academy of Science of London.” As, h

discovery in Chemistry made in Europe or Anglo-America. The history of this medal is as follows :—

Our former illustrious President, Sir Humphry Davy, was presented by the coal-owners of this country with a service of plate, for which they subscribed £2500, in recognition of his merits as inventor of the Safety Lamp. In a codicil to his will Sir Humphry left this service of plate to Lady Davy for her use during her life, with instructions that after her death it should pass to other members of the family, with the proviso that, should they not be in a situation to use or enjoy it, it should be melted and given to the Royal Society, to found a Medal, to be awarded annually for the most important discovery in Chemistry, anywhere made in Europe or Anglo-America.

On Sir Humphry's death the service of plate became the property of his brother, Dr. John Davy, F.R.S., who, in fulfilment of Sir Humphry's intentions, bequeathed it after the death of his widow, or before if she thought proper, to the Royal Society, to be applied as aforesaid. On the death of Mrs. Davy the plate was transferred to the custody of your Treasurer, and, having been melted and sold, realized £738 8s. 5d., which is invested in Madras guaranteed railway stock, as set forth in the Treasurer's balance-sheet. The legacy duty was repaid to the Society by the liberality of the Rev. A. Davy and Mrs. Rolleston.

The style and value of the medal, and the steps to be taken in reference to its future award, are now under the consideration of the Council, and will, I hope, be laid before you on the next Anniversary. The acceptance of the trust has not been decided upon without long and careful deliberation, nor without raising the question of the expediency of recognizing scientific services and discoveries by such trivial awards as medals, and of the extent to which the awards entrusted to our Society are depreciated by their multiplication. My own opinion has long been that some more satisfactory way of recognizing distinguished merit than by the presentation of a medal might be devised, and that the award might take a form which would convey to the public a more prominent and a more permanent record of the services of the recipients, such as a bust or a portrait to be hung on our walls, or a profile or a record of the discovery to be engraved on the medal, which might be multiplied for distribution or sale to Fellows and to foreign Academies. In short, I consider awards of medals without distinctive features to be anachronisms ; it is their purpose, not their value, which should be well marked ; and the question is, whether that purpose is well answered by their being continued under the present form.

*Instruments.*—The small but remarkable and, indeed, classical collection of instruments and apparatus belonging to the Society, and for which there was no accommodation in old Burlington House, was, on our migration from Somerset House in 1857, by order of the Council, deposited in the Observatory in the Kew Deer-Park, near Richmond, then under the control of the British Association.

The instruments have been now for the most part brought back and placed in our Instrument-Room, and will, I hope, at no distant period be accessible to the Fellows.

On the motion of General Smythe, seconded by Mr. Francis Galton, it was resolved—"That the thanks of the Society be returned to the President for his Address, and that he be requested to allow it to be printed."

I now pass to the presentation of the Medals.

The Copley Medal has been awarded to Prof. Louis Pasteur, one of our Foreign Members, "for his researches on Fermentation and on Pebrine."

Prof. Pasteur's researches on fermentation consist essentially of two parts:—the first part, in which he enters exhaustively into the examination of the products formed in this process; and the second, in which he takes up the question of the cause of fermentation.

Previous observers had noticed the production, in solutions of sugar which had been fermented, of substances other than the two commonly recognized, alcohol and carbonic acid; but it remained for Pasteur to show which were essential, and which were occasional products. In the series of able papers contributed to the '*Comptes Rendus*' and to the '*Annales de Chimie et de Physique*,' he proved conclusively that succinic acid and glycerine were always found in fermented solutions of sugar, while lactic acid and acetic acid, although occasionally present, were not always so. He also showed that, in addition to these substances, a part of the sugar was converted into cellulose and fat.

The study of the products formed during fermentation opened the way to the second part of the research, viz. the cause of fermentation.

It had been found that certain solutions, when exposed to the air, soon became full of living organisms; and Pasteur's experiments led him to support the view that these organisms originated from the presence of germs floating in the air. He found that no living organisms were developed if care were taken to destroy completely all those which might be present in the solution, and if the solutions were then carefully sealed up free from air. Nor was it necessary to exclude the air, provided that pure air, free from germs, were admitted. By passing the air through red-hot tubes or through gun-cotton before reaching the solutions, he found that the development of organisms, in such boiled solutions, did not take place. An exception to this was noticed in the case of milk, which required to be heated to a higher temperature than the boiling-point of water at atmospheric pressure. Pasteur showed that this was connected with the alkaline reaction of milk, for in all cases in which the development of life was prevented by heating to the boiling-point of water, the solutions

had a faintly acid reaction—but that when this was neutralized by carbonate of lime, the solutions then behaved like milk.

Prof. Pasteur also examined the gun-cotton through which the air has been passed; and he found, among other things, certain cells to which he attributed the power of causing the growth of organisms in solutions. By sowing some of these cells in solutions which previously had remained clear, and finding that such solutions speedily became turbid from the growth of living organisms, it was proved that the air which had passed through the gun-cotton had lost its property of causing the development of life in solutions because the germs which the air contained had been stopped by the gun-cotton.

The result of the second part of the research may be thus summed up:—

1. No organisms are developed in solutions if care be taken to prevent the possibility of the presence of germs.

2. This negative result does not depend upon the exclusion of oxygen.

3. The matter separated from ordinary air is competent to develop organisms in solutions which previously had remained unchanged.

Not less important were the results of Pasteur's experiments respecting the chemical functions of the ferment.

It had been held that the entire ferment was in a state of putrefactive decomposition, and induced a similar decomposition in the sugar with which it was in contact.

In corroboration of this view, it was stated that ammonia (a product of the decomposition of albuminous substances such as those present in the ferment) is always found in liquids which are undergoing fermentation.

Pasteur proved that the ammonia in fermenting liquids diminishes in quantity in proportion as the process advances, and that the yeast-cells increase and grow while forming complex albuminous substances at the expense of the ammonia and other aliments which are supplied to it. He found that, in addition to ammonia and sugar, the cells require mineral substances, such as phosphates and other constituents, such as are present in the organism of every healthy and growing yeast-cell.

In short, he proved that those conditions which are most favourable to the healthy growth and development of the yeast-cells are most conducive to the progress of fermentation, and that fermentation is impeded or arrested by those influences which check the growth or destroy the vitality of the cell.

The above results are but samples of the fruits of Pasteur's long series of researches in this subject. Many and many an able investigator had worked in the same field; and such were the difficulties they encountered, that Dumas himself recommended Pasteur not to waste his time in working at so hopeless a subject.

To the biologist, two of Pasteur's researches are of very great interest and importance. He has shown that *Fungi* find all the materials needed for their nutrition and growth in water containing an ammonia salt and

The Rumford Medal has been awarded to M F.R.S., "for his Spectroscopic Researches on Chemical Elements."

Mr. Lockyer has long been engaged in spectroscopy of the sun. His first observations were directed to a study of sun-spots as compared with that of the general surface, to bring evidence to decide between two rival theories of their formation. In the course of the paper in which his results were described, and which was read before the Royal Society on the 15th, 1866, he asks, "May not the spectroscopic evidence confirm the existence of the 'red flames' which total eclipse reveals in the sun's atmosphere, although they escape all other observation at other times?"

The spectroscope he then employed proved to be of insufficient power for his researches, and he was induced to apply to the Government-Grant Committee of the Royal Society for aid to obtain greater power. This aid was accorded, and the instrument, though not quite complete, on the 16th of October, 1868, his efforts were crowned by the detection of a solar spectrum of the bright lines exhibited in its spectrum. An account of this was immediately communicated to the Royal Society and the Academy of Sciences.

Meanwhile had occurred the total solar eclipse of August 17, 1868, to observe which various parties had gone out armed with instruments, and especially with spectroscopes, for determination of the hitherto unknown spectrum of the prominences. The results of their labours had been published in the

A discovery like this opened up a new field of research, which Mr. Lockyer was not backward in exploring. One of the firstfruits of the application of the method was the discovery of a continuous luminous gaseous envelope to the sun, which he calls the chromosphere, of which the prominences are merely local aggregations. Evidence was further obtained of gigantic convulsions at the surface of the sun, which were revealed by slight alterations of refrangibility in the lines, observed in a manner similar to that in which Mr. Huggins had determined the relative velocity of approach or recess of the Earth and Sirius.

The interpretation of spectroscopic solar phenomena required a reexamination in several respects of the spectroscopic features of artificial sources of light. Among these researches special mention must be made of Mr. Lockyer's classification of the lines due to the metals of the electrodes between which an induction discharge was passed, according to their "length," i. e. the distance from the electrodes to which they could respectively be traced. This led to the explanation of various apparent anomalies as to the presence or absence of certain dark lines in the solar spectrum, and to the detection of additional elements in the sun, especially potassium, an element which, though so common on the earth and so easily detected by spectral analysis, had not previously been proved to exist in the sun, because the attention of observers had been turned in a wrong direction, as was shown by these researches.

Nor was it only in relation to solar physics that these researches bore fruit. They led to a *quantitative* determination in many cases, by means of the spectroscope, of the proportion of the constituents in an alloy, and afforded new evidence of the extent to which impurities are present even in substances deemed chemically pure.

The Medal was received by Mr. Lockyer.

A Royal Medal has been awarded to Mr. Henry Clifton Sorby, F.R.S., "for his Researches on Slaty Cleavage and on the minute Structure of Minerals and Rocks; for the construction of the Micro-Spectroscope, and for his Researches on Colouring-matters."

The principal grounds on which Mr. Sorby's claims to a Royal Medal rest are the following:—

1. His long-continued study, and his successful application of the microscope to the solution, of problems in petrology.
2. His employment of the prism in conjunction with the microscope for the analysis of the colours transmitted by substances, as well organic as inorganic.

Though Mr. Sorby's labours during the last ten years have been more particularly devoted to observations of the latter class, his work, extending over a period that commenced in 1849, is represented in the Catalogue of Scientific Papers (limited by the year 1863) by no less than 47 memoirs. Among the more remarkable of these must be mentioned the

the British Association and the contributions to the *Philosophical Magazine* (1853, 1856, 1857), in which he grappled with the theory of cleavage, and helped to establish the explanation that the result of greater relative condensation of the material perpendicular to the cleavage, due in the case of rocks to compression in that direction—an idea that met with immolation from other experimentalists.

His work on the temperatures and pressures at which certain rocks were formed (in the *Geological Society's Journal*, 1858), the relative volume of the liquid and vacuous portions of igneous rocks, follows, or, again, on the character of microscopic substances in the mineral matter he investigated, convinced the geologist to take into account the action of water under high pressures and temperatures in explaining the formation of granitoid rocks. The refinement of the methods that Mr. Sorby employed for making thin sections at Sheffield has made those methods the models sought by the now large school of Continental and English microscopic geologists.

The application of spectroscopic methods to the microscope fall more within the limit of ten years, as they have been worked out since Mr. Sorby first described his adaptation of the spectroscopic microscope, as carried out by Mr. Browning.

It is to be regretted that the progress he has made with this instrument, and generally by

and the extent and novelty of the observations which they contain, but by reason of the breadth of view and the philosophical spirit which pervade them.

His labours in Vegetable Palaeontology are above all remarkable, being alike laborious, searching, and productive of important results. These are embodied in six contributions (of which the last will soon appear) to the Philosophical Transactions upon the organization of the Fossil Plants of the Coal-measures—and one on the restoration of a Cycadeous tree (*Zamia gigas*) from the Yorkshire Oolite, published in the Transactions of the Linnean Society. These are not only models of laborious research and exact description, but they are illustrated by more than fifty plates, devoted to microscopic analyses of vegetable tissues, obtained by making transparent slices of the fossils. Both the slices and the drawings are made by Prof. Williamson himself, who thus, to his reputation as a biologist, unites those of an accomplished artist and a skilful lapidary, qualifications which should be named along with those for which the medal is awarded, because no unscientific lapidary could have obtained equally illustrative sections, and no common artist could have depicted them with equal exactitude. The more important results thus obtained refer to the structure, affinities, and reproductive organs of *Calamites* and its allies, to *Lepidodendron*, *Sigillaria*, *Lepidostrobus*, *Asterophyllites*, and to other genera of the Carboniferous epoch.

In addition to these contributions to the history of previously known genera of that epoch, Prof. Williamson has been able to show, on the one hand, that groups of now living plants which were not previously supposed to have a great geological antiquity, actually flourished during the Carboniferous period, and, on the other, that plants of that period which had been previously referred with confidence to groups now living, have in reality other and widely different affinities.

The Medal was received by Prof. Williamson.

The Statutes relating to the election of Council and Officers having been read, and Mr. A. J. Ellis and Col. Strange having been, with the consent of the Society, nominated Scrutators, the votes of the Fellows present were collected, and the following were declared duly elected as Council and Officers for the ensuing year:—

*President.*—Joseph Dalton Hooker, C.B., M.D., D.C.L., LL.D.

*Treasurer.*—William Spottiswoode, M.A., LL.D.

*Secretaries.*— { Prof. George Gabriel Stokes, M.A., D.C.L., LL.D.  
 { Prof. Thomas Henry Huxley, LL.D., Ph.D.

*Foreign Secretary.*—Prof. Alexander William Williamson, Ph.D.

*Other Members of the Council.*—Prof. J. Couch Adams, LL.D.; the Duke of Devonshire, K.G., D.C.L.; Capt. Frederick J. O. Evans, R.N.,

... of the Society were given to the

*Report of the Kew Committee for the Year ending  
October 31, 1874.*

**Magnetic Work.**—The Magnetograph instruments were dismantled in January 1874 for the purpose of thorough examination and readjustment, as was announced in last Report. The necessity for this measure is obvious, when it is remembered that the instruments had been in uninterrupted action for the period of fifteen years.

The scale-values were accordingly redetermined, and the instruments handed over to Mr. Adie for examination and repair. They were returned and remounted in May, but have not been set in continuous action as yet, inasmuch as it is intended that the automatic records should be suspended for the entire year, so as to commence a new series of observations with the year 1875. The cost of these operations has been £77 10s.

The monthly observations with the absolute instruments have been continued, as usual, by Mr. G. M. Whipple, who also takes charge of the general magnetic work, in which he has had the assistance, for the first part of the year of Mr. Cullum, and latterly of Mr. Power.

As regards the Magnetic Reductions, the Tabulations of Declination have been completed up to the end of 1873; and copies of the results to 1872 have been intrusted, for discussion, to the two Sergeants of the Royal Artillery, formerly in Sir E. Sabine's office at Woolwich, who have been in constant attendance at Kew since Nov. 1871. The Tabulations of Inclination and Horizontal Force have not been effected.

Magnetic data have been supplied to Dr. Wijkander, of Stockholm, in connexion with the Swedish Expedition to Spitzbergen, M. Diamilla Müller, of Florence, and Capt. Creak, R.N.

A Unifilar and Dip-circle have been repaired for use at the Observatory, and another pair of similar instruments have been lent to the Rev. S. J. Perry, F.R.S., for use at Kerguelen Island, on the Transit of Venus Expedition, as mentioned in last Report.

*Meteorological Work.*—The several automatic arrangements for recording respectively the Barometer, the Dry- and Wet-Bulb Thermometers, the Anemometer, and the Rain-gauge, have been maintained in constant action under the superintendence of Mr. T. W. Baker, assisted by Mr. Foster and Mr. Figg; and the daily standard eye-observations for control of the photographic records have been made regularly.

The instrumental traces with hourly tabulated values are sent monthly to the Meteorological Office as in former years. The Barograms and Thermograms are obtained in duplicate, and one copy is preserved at Kew. As regards the Anemograms and Hyetograms, the copy is obtained by the method of tracing.

In addition to the regular work of Kew as one of the self-recording Observatories in connexion with the Meteorological Office, the duty of examining and checking the work of all the seven Observatories of the same character has been carried on, in accordance with the method described in the Report of the British Association for 1869. This portion of the work has been performed by Messrs. Cullum, Hawkesworth, and Deane.

A series of investigations have been conducted with the view of testing the degree of accuracy attainable in the tabulation of the Thermograms by the process described in the British-Association Report just referred to. It has been found to be an improvement to set the glass tabulating-scale by means of fiducial lines traced on the Thermograms by photographic means, in preference to setting it, as heretofore, by standard readings. The great advantage derived from the new method is the discovery of "bagging" whenever it exists in the curves.

*Electrometer.*—The Self-recording Electrometer, which had been taken to Glasgow for alteration, as described in last Report, was returned by Mr. White in February, and was adjusted for action on March 10. It has since continued in satisfactory working order.

*Photoheliograph.*—A necessity for reexamining the measurements of the series of Kew sun-pictures having arisen, they have been retransferred to Kew by Mr. De La Rue, and their reexamination has been undertaken, at his expense, by Mr. Whipple, assisted by Mr. M'Laughlin, who has been temporarily engaged for this purpose.

The eye-observations of the sun, after the method of Hofrath Schwabe, have been made daily by Mr. Foster, when possible, as described in the Report for 1872, in order, for the present, to maintain the continuity of the Kew record of sun-spots.

*Extra Observations.*—The Committee, at the request of Prof. Roscoe, F.R.S., undertook to test for a year an instrument which he had devised for measuring the chemical intensity of daylight, as described in the 'Proceedings of the Royal Society,' vol. xxii. p. 158. The apparatus was completed for trial in September, but a few preliminary experiments showed that it required further adjustment; so that operations in this

direction are suspended for the present, to be resumed as soon as the instrument is in a satisfactory condition.

The daily record of temperature from Thermometers at different elevations on the Pagoda in the Royal Gardens, Kew, at the expense of the Meteorological Committee, was continued up to August, when it was interrupted, to be resumed during the winter months.

*Verifications.*—This department of the Observatory has exhibited increased activity, especially as regards the verification of Thermometers and the construction of Standard Thermometers.

The following magnetic instruments have been verified :—

Constants have been determined for

A Unifilar	for Prof. J. Clerk Maxwell, F.R.S.
"	" Prof. Balfour Stewart, F.R.S.
"	" Rev. S. J. Perry, F.R.S.
"	" Mr. P. Adie.
A Magnet	" Lisbon Observatory.
"	" Prof. Buys Ballot, Utrecht.
"	" Prof. Smirnow, Kasan.
3 Magnets	" Kew-Observatory stock.

The following instruments have been verified :—

2 Dip-circles	for Mr. Casella.
1 Dip-circle	" Prof. Wild, St. Petersburg.
1 "	" The Imperial Admiralty, Berlin.
2 Fox's Circles	" " " "
2 Needles	" Prof. Smirnow.
2 "	" Dr. E. van Rijckevorsel.
1 "	" H.M.S. 'Challenger.'
3 Azimuth Compasses	for the Royal Geographical Society.

The complete set of Magnetographs for the Rev. A. M. Colombel, S. J. for Zi-ka-wei, near Shanghai, have been verified and forwarded to their destination.

A set of similar instruments has been ordered by Capt. Pujazon for the Marine Observatory of San Fernando, near Cadiz.

The part of this work which relates to Meteorology is entrusted to Mr. Baker. The meteorological instruments which have been verified are as follows :—

Barometers, Standards	110
" Marine and Station	40
	<hr/>
	150
Aneroids	10

Thermometers, ordinary Meteorological .....	1471
„ Boiling-point Standards .....	22
„ Mountain .....	32
„ Clinical .....	1255
	<hr/>
	2780

In addition, thirty-six Thermometers have been tested at the freezing-point of mercury, and one metallic Thermometer has been tested.

Eighteen Kew Standard Thermometers have been calibrated and divided at Kew.

The following miscellaneous instruments have also been verified:—

Rain-gauges .....	13
Robinson's Dial Anemometers .....	14
Telescope .....	1
Sextant .....	1
Theodolite .....	1
Hydrometers .....	66

A Barograph and Thermograph have been verified for Mr. Kingston for the Observatory at Toronto, and the values of the Scales have been determined as far as practicable.

Experiments have been made with a view to the construction of an apparatus devised by Mr. F. Galton, F.R.S., for facilitating the verification of thermometers, and also for rendering it possible to extend the range to which the Kew verifications at present apply.

A large stock of filled Thermometer-tubes for the construction of Standards has been laid in, and the tubes have been annealed.

In the last Report mention was made of certain experiments in progress with respect to the testing of Anemometers, a piece of ground having been rented in the Park for erecting the instruments.

The experience of a few months was sufficient to show that the exposure in the Park was not nearly sufficiently open to afford facilities for testing the instruments at any but very low velocities, and not very satisfactorily even in such cases. Application was therefore made to the Secretary of the Crystal Palace Company for permission to employ a rotary machine driven by steam-power, so as to be able to vary the velocities at pleasure.

Consent having been most freely given, the experiments were commenced, and the instruments tested at various velocities up to about 30 miles an hour, the highest attainable by the apparatus. The investigations were interrupted during the summer, and will be resumed on a future occasion. It is hoped that by this method of artificial rotation, which was that employed by Smeaton in his experiments on windmill sails, more satisfactory results will be attained than it is otherwise possible to

get. The expense of these experiments has been defrayed by a vote of the Government-Grant Fund.

The experiments on the vibration of pendulums, which were conducted by Capt. Heaviside, R.E., in connexion with the Great Trigonometrical Survey of India, as mentioned in the last Report, were completed at the end of May. The apparatus employed in the experiments, with the exception of the Russian pendulums and their accessories, was, at the request of Prof. G. G. Stokes, F.R.S., received at Kew for storage.

The apparatus for testing Sextants, which had been temporarily removed in 1873 to afford space for swinging the Russian pendulums, has now been restored. The entire cost of this restoration and all other expenses connected with these pendulum experiments have been defrayed by the India Office.

The collimators of the Sextant Testing-apparatus have been arranged so as to be illuminated by gas-jets.

Waxed paper for photographic purposes has been supplied to the Meteorological Office (3 reams), the India Office (1 ream), the Magnetic Observatory, Toronto (4 reams), the Central Observatory, St. Petersburg (1 ream), the Hohe Warte, Vienna ( $\frac{1}{2}$  ream), the Observatory of Don Luiz, Lisbon ( $\frac{1}{2}$  ream).

It has been found necessary to make a change in the arrangements for obtaining waxed paper. For many years, through the kindness of a firm, the paper waxed at Kew has been hot-pressed at a nominal charge, but it was not found possible to continue this arrangement for an indefinite period. Waxed paper has now to be purchased, ready-made, at a considerable increase of cost, and the rate at which it is supplied to observatories has been consequently proportionately increased.

Mr. M'Clatchie and Mr. Beazeley, gentlemen holding appointments in the Chinese Customs Departments, and Mr. Steventon, appointed Assistant to the Observatory at Mauritius, have received instruction in the manipulation and methods of testing both Meteorological and Magnetical instruments, and the management of the photography of the self-recording apparatus.

In the month of September the Superintendent was informed by the President of the Royal Society that that body was prepared to remove the instruments belonging to it, which had been deposited at Kew for storage in Sept. 1851. Accordingly, on the 25th of September, they were handed over to Mr. Ladd, Optician, who had been commissioned by the Council to receive them.

The several pieces of Mechanical Apparatus, such as the Whitworth Lathe and Planing Machine, procured by Grants from either the Government-Grant Fund or the Donation-Fund, for the use of the Kew Observatory, have been kept in thorough order; and many of them are in constant and the others in occasional use at the Observatory.

*Library.*—In addition to the usual Donations of English and Foreign

... Mr. Rigby, whose re-  
1873, resigned, and Mr. Power was app-  
by the promotion of some of the Junior A-  
Mr. Robert H. Scott, F.R.S., continue  
to the Committee.

*Visitors.*—The Observatory has been h-  
presence of several scientific men of disti-  
mentioned :—

Murchison (Dr. C.), F.R.S. A Treatise on the Continued Fevers of Great Britain. Second Edition. 8vo. London 1873. The Author.

December 10, 1874.

JOSEPH DALTON HOOKER, C.B., President, in the Chair.

The President announced that he had appointed as Vice-Presidents:—

The Treasurer.

The Duke of Devonshire.

Mr. John Evans.

Right Hon. Lyon Playfair.

Dr. Sanderson.

The Presents received were laid on the table, and thanks ordered for them.

The following Papers were read:—

- I. "On the Development of the Teeth of the Newt, the Frog, and certain Lizards." By CHARLES S. TOMES, M.A. Communicated by JOHN TOMES, F.R.S. Received July 23, 1874.

(Abstract.)

That the "papillary stage" of tooth-development could not be said to at any time exist either in the frog or in certain fish, was pointed out nearly twenty years ago by Professor Huxley, who, however, accepted, on the authority of Goodair, the latter's theory of the process as true of Man and Mammalia. In more recent years Kölliker and Waldeyer have traced out the course of the development of teeth with great accuracy in Man and some other Mammalia, with the result of showing that the usually accepted views propounded by Goodair and Arnold are not by any means an accurate representation of what takes place in them.

Since the date of the publication of Professor Huxley's paper, I am not aware that any thing has been published bearing upon the development of the teeth of Reptilia and Batrachia, save a paper by Dr. Lionel Beale upon the development of the teeth of the Newt, and a short and inconclusive paper by Santi Sirena; with the exception of the papers alluded to, the subject may be taken to stand in the position which it occupied at the time of the publication of Professor Owen's 'Odontography,' in which we are told that the teeth-germs of Reptiles and Batrachia never stop at the papillary stage, but that the primitive dental papilla sinks into the substance of the gum and becomes inclosed by a capsule.

The principal facts which my observations enable me to state are:—

That there is no such thing as a "dental groove" or "dental fissure" in the Batrachia and Sauria, but that the whole process takes place beneath an unbroken surface of epithelium.

That there is no such thing as a stage of "free papillæ," and consequently no sinking of papillæ into the gum and subsequent encapsulation of the same.

Instead of being formed in a "dental groove" the teeth are developed in a region which may be termed the area of tooth-development, varying in form and extent in different Reptilia, but agreeing in all in possessing the following characters:—

It is bounded on the one side by the teeth in place and the parapet of bone which carries them, and on the other, or inner, side by an exceedingly sharply defined boundary, consisting of dense connective tissue. At the surface, near where the functional tooth projects above the oral epithelium, it is narrow, but it expands as it passes more deeply below the surface. Within this area are developing tooth-sacs of different ages, the interspaces being occupied with a loose areolar tissue, differing in appearance from that which is seen outside the area, and appearing to be derived from portions of older tooth-sacs, which have not been entirely used up in the formation of the teeth.

The individual tooth-sacs are formed thus: an inflection of the cells of the oral epithelium, in section like a tubular gland, passes down along the inner side of the area above defined, until it reaches nearly to the level of the floor of the area. The depth to which it penetrates is considerable in many forms, *e. g.* in the Lizards, in which, therefore, this double layer of epithelial cells appears a mere line.

At the bottom of this inflection of epithelial cells the adjacent tissue assumes the form of a small eminence (without at first any visible structural alteration), while the epithelial process takes the shape of a bell-like cap over the eminence.

This epithelial inflection then goes to form the enamel-organ; the eminence becomes the dentine-organ.

Thus the enamel-germ is the first thing recognizable, and the presence of this ingrowth of epithelial cells seems to determine the formation of a dentine-organ at that particular spot which lies beneath its termination.

The enamel-organs, after they are fully formed, retain a connexion with epithelial cells, external to the ovoid or spherical tooth-sacs, at their summits; and the enamel-organs of successive teeth appear to be derived from the necks of those of their predecessors rather than from fresh inflections from the surface of the oral epithelium, though I am not sure that this is, in all instances, the case.

The tooth-sac of the newt is entirely cellular, and has no special investment or capsule; under pressure it breaks up and nothing but cells remain, as was noted by Dr. Lionel Beale.

That of the frog has an investment, derived in the main from what may be called the accidental condensation of the surrounding connective tissue, which is pushed out of the way as it grows; while in the lizard

the base of the dentine-germ furnishes lateral prolongations, just as has been observed to be the case in man.

The dentine-organs conform closely with those of mammals; the odontoblast layer is very distinct, and the processes passing from these cells into the dentine-tubes are often visible.

The enamel-organs consist only of the outer and inner epithelia, without any stellate intermediate tissue; as, in some instances, enamel is certainly formed, the existence of the stellate tissue is obviously non-essential. When a tooth is moving to displace its predecessor, its sac travels with it, remaining intact until the actual attachment of the tooth to the bone by ankylosis.

II. "On the Structure and Development of the Teeth of Ophidia." By CHARLES T. TOMES, M.A. Communicated by JOHN TOMES, F.R.S. Received October 5, 1874.

(Abstract.)

Contrary to the opinion expressed by Professor Owen and endorsed by Giebel and all subsequent writers, the author finds that there is no cementum upon the teeth of snakes, the tissue which has been so named proving, both from a study of its physical characters and, yet more conclusively, from its development, to be enamel. The generalization that the teeth of all reptiles consist of dentine and cement, to which is occasionally added enamel, must hence be abandoned.

Without as yet pledging himself to the following opinion, the author believes that in the class of Reptiles the presence of cementum will be found associated with the implantation of the teeth in more or less complete sockets, as in the Crocodiles and Ichthyosaurs.

The tooth-germs of Ophidia consist of a conical dentine-germ, resembling in all save its shape that of other animals, of an enamel-organ, and of a feebly expressed capsule, derived mainly from the condensation of the surrounding connective tissue.

The enamel-organ consists only of a layer of enamel-cells, forming a very regular columnar epithelium, and of a few compressed cells external to this, hardly amounting to a distinct layer; the enamel-organ is coextensive with the dentine-germ. There is no stellate reticulum separating the outer and inner epithelia of the enamel-organ.

The successional teeth are very numerous, no less than seven being often seen in a single section; and their arrangement is peculiar, and quite characteristic of the Ophidia.

The tooth next in order of succession is to be found at the inner side of the base of the tooth in place, where it lies nearly horizontally; but the others stand more nearly vertically, parallel with the jaw and with the tooth in place, the youngest of the series being at the bottom.

*on the Development of the Teeth of Ophidia.* [Dec. 10,

row of tooth-sacs is contained within a single general con-  
investment, which is entered at the top by the descending  
epithelium, whence the enamel-germs are derived.

in considerable length, the forming teeth, which were at  
become nearly horizontal, resuming, of course, their upright  
more when they come into place.

the whole peculiarity of this arrangement is to be found in  
ilatation which the mouth of the snake undergoes. The  
ar investment probably serves to preserve the tooth-sacs  
ment; while, if the forming teeth remained vertical after  
ned to any considerable length, their points would be pro-  
h the mucous membrane when this was put upon the stretch  
ing of prey.

author has shown in a previous communication to be the  
trachia and Sauria, the hypothetical "papillary stage" is at  
nt.

ral epithelium there extends downwards a process which,  
en and winding around the older tooth-sacs, after pursuing  
arse, reaches the furthest and lowest extremity of the area  
opment. Here its caecal end gives origin to an enamel-  
hile it does so, buds forth again beyond it in the form of a  
tv. Thus at the bottom of this area of tooth-development  
tual formation of fresh enamel organs, beneath which

III. "On the Effects of Heat on Iodide of Silver." By G. F. RODWELL, F.R.A.S., F.C.S., Science Master in Marlborough College. Communicated by Professor FREDERICK GUTHRIE, F.R.S. Received August 14, 1874.

Professor Clerk Maxwell, when discussing the expansion of matter by heat ('Theory of Heat,' p. 8), says, "The body generally expands (the only exception among solid bodies, as far as I am aware, is the iodide of silver, which has been found to contract as the temperature rises)." M. H. Fizeau, speaking of the same substance ('Nouvelles Observations relatives à l'iodure d'argent'), writes as follows:—"Ce corps, en effet, paraît offrir l'exemple d'une inversion complète des phénomènes ordinaires de la dilatation par la chaleur, car son volume diminue très-certainement pendant l'échauffement et augmente pendant le refroidissement."

It was thought that a substance possessing so marked a property would probably exhibit peculiarities of molecular structure; and the following experiments were made in order to determine whether such peculiarities exist, to note the effects of higher temperatures upon the iodide than those employed by Fizeau (which in no instance exceeded  $100^{\circ}$  C.), and to determine the point of maximum density of the iodide. The phenomena which most closely approximate to those assigned to the iodide of silver when heated are to be found in the case of the anomalous expansion of ice and bismuth, and a few other substances which at the moment of fusion, and for a few degrees above their point of solidification, exhibit contraction on being heated; but in these instances we have to bear in mind that a change of state is simultaneously effected, or about to be effected, in the substance. Again, certain crystals contract in the direction of one of their axes on the application of heat; but they expand in the direction of another axis, and the total expansion is greater than the contraction, so that they possess a positive coefficient of expansion. Garnets and a few other crystals undergo an increase of specific gravity on being strongly heated, and slowly recover their original density.

The iodide of silver, on the other hand, when far removed from the point at which it undergoes any change of state, appears to exhibit contraction, to possess what M. Fizeau calls a "negative coefficient of expansion;" and this is the more remarkable when we remember that the chlorides, bromides, and iodides of potassium, sodium, and ammonium, and the chloride and bromide of silver expand considerably when heated, more so, indeed, than the most expansible metals, such as lead, tin, and zinc. The contraction of the iodide of silver is, according to Fizeau, quite regular between  $-10^{\circ}$  C. ( $14^{\circ}$  F.) and  $+70^{\circ}$  C. ( $158^{\circ}$  F.); and he calculates that the contraction is equal to about  $\frac{1}{1000}$  of its volume at  $0^{\circ}$  C. for  $100^{\circ}$  C., or, again, equal to one sixth

of platinum for  $100^{\circ}$  C. He also found that a large crystal exhibited a very considerable contraction in the direction of symmetry, while a slight expansion was produced in a direction perpendicular to the axis of the crystal\*. The contraction was the same both of the crystal, a confused crystalline mass, and a mass produced by strongly compressing the precipitated iodide. It became a hard mass capable of receiving a fine polish, and had a specific gravity of 5.569. Fizeau considers that the iodide has its maximum of volume or minimum of density at a temperature of  $-76^{\circ}$  C. ( $-76^{\circ}$  F.).

The silver employed in the following experiments was prepared by precipitation. Pure iodide of potassium was added to silver, both in dilute solution. The precipitated iodide was washed in the dark, slowly dried, fused in a porcelain crucible, and formed into cylindrical masses, either in a warm porcelain or brass vessel. By dissolving pure silver in strong hydriodic acid, evaporating to dryness, fusing. (3) By exposing pure silver leaf for some time to the vapour of iodine produced by spontaneous evaporation.

To examine the effects of heat upon the iodide, it may be well to mention a few experiments concerning the action of light upon it. A con-

metallic state, and forming an opaque metallic film on the parts of the surface which have been exposed to light."

The following experiments were made to determine the degree of sensitiveness of the iodide to light:—

a. By means of a large lens the rays of the electric lamp were brought to a focus within a glass cell containing a solution of iodide of potassium; a solution of nitrate of silver was then introduced by a pipette at the apex of the cone of rays. The precipitated iodide possessed its usual pale yellow colour.

β. Freshly precipitated iodide in suspension, with a slight excess of iodide of potassium, remained in the full glare of a July sun without undergoing any perceptible change; neither did it subsequently darken.

γ. Freshly precipitated iodide in suspension, with a slight excess of nitrate of silver, underwent no immediate change on exposure to a July sun. At the end of an hour it had become slightly grey, and subsequently darkened.

δ. Organic matter in the shape of starch-paste did not induce any change when mixed with freshly precipitated iodide in suspension with a slight excess of iodide of potassium. Albumenized paper with iodide precipitated upon it did not undergo any immediate change.

e. Some dried and powdered iodide was found to have acquired a slight greyish metallic tinge after an hour's exposure to the sun. A freshly broken surface of fused iodide became very slightly darker after exposure to the sun. A very pale microscopical crystal of iodide, removed from the interior of a crystalline mass, became slightly brown after several hours' exposure to diffused light.

ζ. Crystals of iodide of silver produced by direct solution of silver in hydriodic acid were not affected by light; neither were crystals of hydro-argentic iodide ( $\text{AgIHI}$ ), nor crystals of argento-potassic iodide ( $\text{AgIKI}$ ).

η. A sheet of silver leaf was exposed to the vapour of iodine (produced by spontaneous evaporation) for five minutes; it possessed a faintly yellow tinge, which on exposure to the sun instantly became pale green, but on further exposure returned to its original pale yellow. A second sheet was exposed for ten minutes to the vapour of iodine; it acquired a golden-yellow surface, which on exposure to diffused light acquired a purplish-red colour, and on exposure to the sun became greenish purple. On continued exposure this colour disappeared, and the plate returned to almost the original yellow colour.

θ. A sheet of silver leaf was exposed to the vapour of iodine for half an hour, at the end of which time it possessed a decided golden yellow colour; on exposure to the sun it instantly acquired a dark purple colour, edged with green at those parts least exposed to the direct vapour of the iodine. On continued exposure the purple became paler, but the sheet did not return to its original yellow colour.

ing solution composed of ferrous sulphate, alcohol, acetic acid, when applied to the exposed sheets of  $\eta$  and  $\theta$ , which had been exposed on continued exposure nearly regained their original colour, and  $\theta$  a reddish-brown colour.

A piece of silver leaf was exposed to the vapour of iodine for many days, and was found to be converted into a slightly coherent film of silver iodide. Light had no effect upon it, even after long exposure to July sun; neither was any colour produced on the addition of the developing solution.

A mixture of silver would thus appear to be scarcely affected by light when silver is present, either in the form of nitrate or, as in the case of silver films, as metallic silver.

When precipitated iodide of silver be fused it is found to cool to a brittle mass, which in thin layers is translucent. The surface has a dark steel-grey, semimetallic appearance, but this does not indicate composition. Sometimes, without any apparent cause, the silvery surface and the dark steel-grey may exist side by side in the fused mass. A second fusion may produce a uniformly silvery surface or a uniformly steel-grey surface. But whatever the surface of the fused mass, it always furnishes when pulverized a dark grey powder, which, when heated, remains unaltered in colour up to  $221^{\circ}$  C. ( $421^{\circ}$  F.). At that temperature it begins to darken,

takes place, often accompanied by a loud cracking, and large fissures appear in the mass.

Many attempts were made to determine the precise temperature at which the change from the amorphous to the crystalline condition takes place; but the results were somewhat discordant, depending apparently on the mass of the iodide, and perhaps on the number of times it had been previously fused. The iodide was fused in a glass tube or porcelain crucible, and when fusion was quite complete was placed in an air-bath at  $150^{\circ}\text{C.}$  ( $302^{\circ}\text{F.}$ ) and allowed to cool. The exact temperature at which the tube was broken by the expanding mass was noticed. About 15 grammes of iodide, which had been often fused, changed suddenly from the amorphous to the crystalline condition at  $120^{\circ}\text{C.}$  ( $248^{\circ}\text{F.}$ ). Another specimen cracked the tube at  $116^{\circ}\text{C.}$  ( $240^{\circ}\cdot 8$ ). A porcelain crucible containing 10 grammes of the fused iodide commenced to change at  $118^{\circ}\text{C.}$  ( $244^{\circ}\cdot 4$   $\text{F.}$ ); the crucible was violently riven open at  $105^{\circ}\text{C.}$  Two small test-tubes, about 6 millimetres diameter and each containing 2 grammes of iodide, were placed in the hot-air bath; the two masses of iodide simultaneously changed to the crystalline condition at  $109^{\circ}\text{C.}$  ( $228^{\circ}\cdot 2$   $\text{F.}$ ). On one occasion a small mass weighing 3 grammes, prepared by dissolving silver in hydriodic acid, was fused in a tube and slowly cooled. It cooled down to the ordinary temperature of the air without breaking the tube; on moving the tube, however, the mass suddenly underwent molecular change, and the tube was broken. The same iodide fused with some which had been similarly prepared suddenly changed to the crystalline variety at  $121^{\circ}\text{C.}$  ( $249^{\circ}\cdot 8$   $\text{F.}$ ). From the above results we cannot be far wrong in stating that the change from the amorphous to the crystalline variety of the iodide takes place at a temperature of about  $116^{\circ}\text{C.}$  ( $240^{\circ}\cdot 8$   $\text{F.}$ ).

Presumably heat is evolved when the amorphous modification of the iodide passes into the crystalline. Several attempts were made to ascertain this by plunging a mass of hot amorphous iodide into hot mercury, inserting a thermometer, and allowing the whole to cool, but no rise of temperature was observed at any given point of the cooling.

If the fused iodide be cast into a tube of porcelain or brass the following effects may be observed:—( $\alpha$ ) The mass contracts considerably at the moment of solidification, the level liquid surface sinking into a deep conical depression when it becomes solid. ( $\beta$ ) For many seconds after the solidification the solid cylinder of iodide will freely slip out of the tube, and is then seen to be red and transparent, in fact in the amorphous condition; but ( $\gamma$ ) if the mass cools until it assumes the crystalline condition it can no longer be got out of the tube; and if the latter be of glass or porcelain, it is infallibly broken by the expansion. Hence if a mass of iodide be allowed to cool in a tube which it cannot break when it expands, it may be made to contract and slip easily out of the tube by heating it. Hence also, as the change from the amorphous

ne condition takes place at  $116^{\circ}\text{C.}$ , it would appear that  
nt of fusion,  $450^{\circ}\text{C.}$  (p. 100), and the temperature at which  
s iodide becomes crystalline it follows the ordinary law  
as it cools, while below that temperature (and, as will be  
as  $-18^{\circ}\text{C.}$ ,  $-0^{\circ}\cdot4\text{ F.}$ ) it expands on getting cooler, and  
gative coefficient. It thus appears that when the iodide is  
ous condition at  $116^{\circ}\text{C.}$ , immediately before the change to  
condition, it is at its point of maximum density.

successful attempts were made to burst metal bottles, after  
the familiar ice-experiment, by the expansion of the iodide  
when it passes from the amorphous to the crystalline con-  
ne occasion, when a somewhat large cylindrical mass had  
tube of thin brass, the latter was burst by the expanding  
ck metal bottles, furnished with a screw, which was forced  
e molten mass, were not broken. Thick porcelain and  
re invariably broken by the expansion; and a good lecture  
illustrate the anomalous expansion is furnished by the  
as. Let 20 or 30 grammes of fused iodide be cast into a  
al tube of porcelain a centimetre diameter; in the course  
r two the mass has cooled down to the temperature at  
s from the amorphous to the crystalline condition, it then

of the iodide. This would give as the specific gravity of the molten iodide 5.406. The mass was then allowed to solidify in the tube, and a large conical cavity appeared at the moment of congelation. This cavity contained 4.552 grammes of mercury, and would contain 1.8149 gramme of iodide. Hence, if the volume of the iodide before fusion be taken as 100, the volume of the resulting fused iodide will be 104.499. Or, again, 100 volumes of molten iodide contract to 95.694 volumes of the solid. The principal expansion takes place at the moment of fusion, and the expansion between  $116^{\circ}$  C. and  $450^{\circ}$  C. is not considerable. No really satisfactory method has been yet found for determining the coefficient of expansion between  $116^{\circ}$  C. and  $450^{\circ}$  C.; but if we assume it to be equal to the mean expansion on the other side of  $116^{\circ}$  C. (of course omitting the sudden expansion which takes place when the amorphous passes into the crystalline condition), we find that a volume 1.00000 at  $116^{\circ}$  C. will become a volume of 1.01455238 at  $450^{\circ}$  C. just below the melting-point, while in passing from the solid to the liquid condition the volume increases from 1.01455 to 1.04499, an expansion = .03044.

When a mass of iodide of silver passes from the amorphous into the crystalline condition the molecular commotion is so considerable that portions of the mass are sometimes jerked off from the ends of a bar, and large fissures appear in the mass. These are sometimes as much as half a millimetre broad and several centimetres long in a cylindrical mass weighing from 10 to 20 grammes. They penetrate to the centre of the mass, as may be shown by cooling the iodide under mercury, when the whole mass is found to be permeated by the metal. The capacity of these intercrystalline spaces was determined by allowing a known weight of iodide to pass from its amorphous to its crystalline condition beneath the surface of mercury, and again weighing.

$\alpha$ . 3.643 grammes AgI after thus cooling weighed 3.968 grammes.

$\beta$ . 5.913        "        "        "        "        6.417        "

And as we know the specific gravity of mercury and of the iodide, it is easy to deduce from the above that the volume of the cracks is represented respectively by ( $\alpha$ ) .1353 gramme and ( $\beta$ ) .2098 gramme of iodide; hence

$$\alpha. 3.643 : .1353 :: 100 : 3.7112$$

$$\beta. 5.913 : .2098 :: 100 : 3.5481$$

which give a mean of 3.6296. Therefore 100 grammes of iodide in the amorphous condition produce, in passing into the crystalline condition, intercrystalline spaces capable of containing 3.6296 grammes of iodide. From an observation which was made on a cylindrical mass of iodide a centimetre diameter, which in undergoing expansion in the passage from the amorphous to the crystalline condition had produced a separation amounting to half a millimetre in a tube which had yielded to the expansion, the expansion of the mass, *plus* the intercrystalline spaces within

to be  $\cdot 047619$ ; hence a volume of amorphous iodide represented by unity becomes a volume of  $1\cdot 047619$  in passing into the crystalline condition, plus the intercrystalline spaces; and the volume of these spaces has been determined above, we find that the actual change of volume which takes place simultaneously with the change of molecular weight amounts to  $\cdot 011323$ ; that is, a volume of iodide at its point of fusion (116° C.) represented by unity becomes a volume of  $1\cdot 058942$  on changing to the crystalline condition.

Compression and cooling appear to render a mass of iodide more crystalline, and to promote the formation of large fissures. Iodide prepared by dissolving silver in hydriodic acid and subsequent precipitation is brittle than that produced by precipitation and fusion.

We have before noticed that while the latter passes into the crystalline condition at a temperature ranging a few degrees on either side of 116°, the former may sometimes be cooled to much lower temperatures without change; in fact it appears to be altogether more compact and freer from intercrystalline spaces than the fused iodide produced by precipitation, indeed almost perfectly free. The specific gravity of the former is also to be slightly higher. Boullay found the specific gravity of iodide produced by precipitation to be  $5\cdot 61$ ; but he was probably misled by the presence of the intercrystalline spaces, or he did not

and more compact than that produced by precipitation. Deville found the specific gravity of the unfused precipitated iodide to be 5.807, and of the fused iodide 5.687, while Damour found the native crystals to have a specific gravity of 5.667; hence the amorphous precipitate has a higher density than either the fused crystalline iodide and their native crystals. Thus the density of the amorphous precipitate coincides almost perfectly with the density of the fused iodide at its point of maximum density ( $116^{\circ}\text{C.}$ ) when in the amorphous condition, as deduced from the above experiments.

If we place in a specific-gravity flask a quantity of fused iodide of silver, fill it up with mercury (taking every precaution to displace the air from the intercrystalline spaces), and place in the ground neck of the flask a perforated stopper continued as a capillary thermometer-stem, we have obviously a thermometer in which we can observe the effect produced by the anomalous contraction of the iodide on the regularly expanding mercury. On applying heat to such an arrangement we observe that for a while the mercury rises in the stem, until on further heating the contraction of the iodide exceeds the expansion of the mercury, and the column retreats if much iodide is present into the very bulb of the instrument.

If the heating be now discontinued the mercury slowly rises as the iodide cools, until the contraction of the mercury exceeds the expansion of the iodide, beyond which point the mercury continues to sink as the bulb cools. Nothing could better illustrate the complete inversion of the effects usually produced by heat on bodies in the case of the iodide of silver.

Professor Guthrie suggested to me that a convenient method of determining the amount of contraction produced by heat in the iodide would be to fill a specific-gravity flask with mercury, and determine the amounts of mercury exuded from the flask for every ten or twenty degrees of temperature; then to place in the flask a known weight of fused iodide with a known weight of mercury, and repeat the determinations. This was accordingly done. About 440 grammes of mercury were employed, and weighings made at intervals of a few degrees. The method was found to be satisfactory, and the results concordant. For example (to take a few instances from many), the amounts of mercury driven from the flask by expansion for  $10^{\circ}\text{C.}$  were found to be as follows:—

Between	$29^{\circ}\text{C.}$	and	$53^{\circ}\text{C.}$	.....	066062
„	$22^{\circ}\text{C.}$	„	$74^{\circ}\text{C.}$	.....	067250
„	$20^{\circ}\text{C.}$	„	$84^{\circ}\text{C.}$	.....	067390
„	$29^{\circ}\text{C.}$	„	$86^{\circ}\text{C.}$	.....	068526
„	$47^{\circ}\text{C.}$	„	$84^{\circ}\text{C.}$	.....	069297

numbers which, when the necessary corrections have been made for

of the glass, agree very well with Regnault's determination of the absolute expansion of mercury. Then 38.3680 grammes of iodide were placed in the flask; it was filled up with mercury, weighed, heated, cooled in a good vacuum, weighed, cooled to  $-18^{\circ}$  F.) and weighed. The flask was then heated respectively to  $21^{\circ}$  C.,  $67^{\circ}$  C., and the weights determined. At high temperatures the mercury acts upon the iodide and a green iodide of mercury is formed. The results were not very concordant above  $67^{\circ}$  C. and have not been introduced. The general results were as follows: The weight of mercury driven from the flask for  $1^{\circ}$  C. were re-

between $-18^{\circ}$ and $0^{\circ}$ C.	=	.052648
" $-18^{\circ}$ " $+21^{\circ}$ C.	=	.051392
" $0^{\circ}$ " $+21^{\circ}$ C.	=	.050285
" $-18^{\circ}$ " $+67^{\circ}$ C.	=	.049684
" $0^{\circ}$ " $67^{\circ}$ C.	=	.048873
" $+21^{\circ}$ " $67^{\circ}$ C.	=	.048228

Knowing the known weight of mercury in the flask and the known weight of mercury, it is easy to deduce the quantity of mercury which has been driven from the flask by expansion for any number of degrees, having determined the actual amount of mercury ex-

TABLE showing approximately the Action of Heat on Iodide of Silver, between  $-18^{\circ}$  C. and the fusing-point, compared with the Action of Heat on Mercury.

endeavoured to prove in the foregoing pages the following

iodide of silver exists in three allotropic forms, viz. ( $\alpha$ ), between  $116^{\circ}$  C. and its fusing-point, as a plastic, amorphous substance possessing a reddish colour and transparent; ( $\beta$ ), at temperatures below  $116^{\circ}$  C., as a brittle, opaque, crystalline mass; and ( $\gamma$ ), if fused and poured into cold water, as an amorphous, very brittle, yellow, opaque substance.

Iodide possesses a point of maximum density at or about the moment before passing from the amorphous into the crystalline condition.

If we allow a mass of molten iodide to cool, the following is observed:—( $\alpha$ ) at the moment of solidification a very slight contraction takes place; ( $\beta$ ) the solid, on further cooling, contracts in a slight and regular contraction after the manner of solid bodies; and ( $\gamma$ ) at or about  $116^{\circ}$  C. it undergoes sudden and violent expansion, passing from the amorphous into the crystalline condition; on going through this expansion the mass on further cooling undergoes contraction, and ( $\epsilon$ ) the coefficient of contraction diminishes as the temperature decreases (or otherwise expressed, the coefficient of contraction increases with the temperature).

In conclusion, express my great indebtedness to Dr. Guthrie

(37°-75 C.) it begins to soften slightly, and gradually becomes softer as the temperature rises, until just before reaching the fusing-point, 142° F. (61°-11 C.), it is quite plastic, and may be moulded by pressure, or spread out into thin coherent sheets. It thus resembles some metals which are brittle at the ordinary temperature, but become more and more malleable as the temperature rises. As the temperature rises, the paraffine becomes more and more translucent; and, like sealing-wax and some other bodies, it becomes what we may call either semifluid or semisolid before it finally fuses to a colourless perfectly transparent fluid. As the temperature approaches 400° F. (205°-5 C.), the liquid begins to give off fumes; it "flashes" (that is to say, the vapour ignites on the application of flame, but does not continue to burn) at 458° F. (236°-65 C.); and the vapour ignites spontaneously without the presence of flame and continues to burn at 576° F. (302°-75 C.). Finally the boiling-point is above the melting-point of lead and the boiling-point of mercury, but below the melting-point of zinc (apparently not much below it), presumably about 750° F. (398°-8 C.). Air-thermometer determinations of the boiling-point were not satisfactory. As the liquid cools from the boiling-point the contraction is seen to be enormous. The comparatively small quantity of liquid paraffine (about 15 grammes) capable of being contained in a tube 15 centimetres (nearly 6 inches) long by 15 millimetres (nearly  $\frac{5}{8}$  inch) diameter can be seen to sink two or three centimetres in less than 10 minutes. The subsidence continues until the point of solidification is attained, when the mass commences to solidify at the bottom, and proceeds gradually up the sides of the tube, leaving a central core of perfectly fluid matter which does not solidify for some length of time. The mass parts with its heat very slowly. When perfectly and uniformly cooled down to the ordinary temperature, a hollow central core is found in the mass of paraffine, extending nearly to the bottom, and gradually narrowing as it descends. The contraction which takes place in passing from the liquid to the solid condition is very considerable.

The expansion which paraffine undergoes when heated appeared to be so unusually great, that the following experiments were made in order to determine its amount. They may be divided into three parts, viz. experiments to determine:—(a) the coefficient of expansion of the solid for temperatures between 32° F. (0° C.) and the point of fusion, 142° F. (61°-11 C.); (b) the precise change of volume which ensues when the solid at 142° F. passes into the liquid at 142° F.; and (c) the coefficient of expansion of the liquid between its point of maximum density (142° F.) and its boiling-point (presumably about 750° F., 398°-8 C.).

In these determinations the greatest obstacle to be contended against was the slight conductivity of the paraffine, which made it very difficult to evenly heat either a solid or liquid mass. The only way of doing this was to keep the mass for a length of time at the precise temperature required; and this it is almost impossible to do when the temperature of

as is above the point at which the vapour ignites spontaneously, also difficult to manipulate with a liquid which is above the surface of mercury, and is at the same time giving off clouds of inflammable vapour. The slight conductivity of the solid gave the following results. The bulb of a thermometer was immersed in a mass of paraffine in such a manner that the distance between the top surface of the paraffine and the surface of the bulb was 8 millimetres (about 1/3 inch). It was immersed in water, and kept in a fixed position 10 centimetres above the bottom of the beaker, and on a level with the top of the bulb in direct contact with the water. The beaker was placed on a sand-bath, and the thermometers were observed for 10 minutes at intervals of two minutes. At starting, 11.20 A.M., the temperature of the water was 52° F. (11°·11 C.). The gas was turned

out when the thermometer immersed in the water read  $141^{\circ}$  F., but it rose to  $148^{\circ}$  F. (six degrees above the point of fusion of the paraffine), and a very small amount of paraffine at the surface melted; hence, with the exterior surface actually fusing at  $148^{\circ}$  F., it will be seen that the imbedded thermometer, separated from the fused surface by only 8 millims. of paraffine, read  $48^{\circ}$  F. lower. Further, it will be noticed that the temperature of the water rose steadily to  $148^{\circ}$  F. and then sank at the rate of about one degree in a minute, while the paraffine acquired heat increasingly till the water ceased to be heated, then less quickly, until when the paraffine had acquired a temperature of  $130^{\circ}$  F. the temperatures coincide, half an hour after the commencement of heating. Then the temperature of the paraffine begins to fall gradually, and less quickly than that of the water, until at  $90^{\circ}\cdot5$  F. there is once again coincidence, one hour and twenty-seven minutes from the commencement of heating. After this the temperatures read alike, and the thermometers continue to fall *pari passu*. In the column of differences, *minus* differences signify that the temperatures of the paraffine-thermometer were *below* those of the water-thermometer, *plus* differences that the former were *above* those of the latter.

It will be noticed that the two-minute observations cease at 12.10 P.M., and that the last four are made at intervals of 12, 25, 10, and 68 minutes.

In regard to the fluid paraffine, a mass of from 20 to 30 grammes takes two or three hours to cool down from just below its fusing-point to the temperature of the air—that is, to cool through about  $80^{\circ}$  F. The bulb of a thermometer was surrounded by 8 millimetres of liquid paraffine at  $150^{\circ}$  F., and was plunged in a bath kept at  $245^{\circ}$  F.; at the end of half an hour the mass of about 30 grammes had barely acquired the temperature of the bath. In heating a vessel of paraffine there is always a marked difference between the temperatures of the upper and lower levels. The convection-currents part with their heat so slowly that a uniform temperature throughout the mass seems to be altogether unattainable without constant and complete agitation. During the heating of about half a litre of the liquid paraffine in a cylindrical copper vessel 75 millimetres (about 3 inches) diameter by 150 millimetres high, the following results were obtained:—The upper thermometer was placed with its bulb a centimetre from the surface, the lower thermometer with its bulb a centimetre from the bottom. The fluid mass was directly heated by a Bunsen burner from below. In the column of differences, *minus* differences signify that the temperature of the lower thermometer is *below* that of the upper thermometer, and *plus* differences that the temperatures of the former are *above* those of the latter. The gas was turned out at 6 P.M., the highest temperature being attained by the lower thermometer ( $361^{\circ}$  F.) at 6.1 P.M., while the highest temperature attained by the upper thermometer was  $354^{\circ}$  F. at the same time.

Owing to the great contraction which takes place when a mass of liquid paraffine solidifies, it was found to be somewhat difficult to obtain a solid mass free from minute cavities and of uniform texture. The plan eventually adopted was to take a long column of melted paraffine and to cool the lower extremity of it. The supernatant fluid forced its way into the central cavity produced by the contraction of the solidifying mass, and the result was a mass of paraffine apparently quite compact and free from cavities. It was suspended from the balance by horsehair, and weighted by a piece of brass, the weight of which in air and water at different temperatures was known; and the whole was finally weighed in distilled water which had been well boiled and cooled in a good vacuum. After the immersion of the paraffine the whole was again placed in a good vacuum. The mass was heated and weighed in water at various temperatures, between 32° F. (0° C.) and 142° F. (61°·11 C.); the melting-point and the cubical expansion was found to be as follows, for one degree Fahrenheit:—

Between	32° F.	and	60° F. (15°-55 C.)	....	·00031985
"	60° F.	"	100° F. (37°-6 C.)	....	·00039090
"	100° F.	"	120° F. (48°-85 C.)	....	·00143118
"	120° F.	"	142° F. (61°-11 C.)	....	·00244358

The considerable increase of the coefficient as the point of fusion is approached is explained by the fact, already adverted to, that the solid paraffine becomes soft and semisolid like sealing-wax and gutta-percha before actually becoming liquid. From the above coefficients we deduce the fact that

100 volumes of paraffine at 32° F.	become	100·8955	at	60° F.
"	"	"	"	102·4591 " 100°
"	"	"	"	105·3215 " 120°
"	"	"	"	110·6974 " 142°

As the latter temperature is approached the mass may be moulded by the hand like a mass of dough or putty; and on continuing the heat at the same temperature, it fuses to a limpid liquid.

***Determination of the amount of expansion which paraffine undergoes when it passes from the solid condition at 142° F. to the liquid condition at the same temperature.***

Tubes of known weight and capacity were exactly filled with melted paraffine at  $142^{\circ}$ . They were then allowed to cool; the cavity produced by contraction was accurately filled with mercury, which was weighed and the capacity of the cavity deduced therefrom. The results were concordant and satisfactory. Thus it was found that volume=100 at  $60^{\circ}$  F. becomes, in the fluid condition, at  $142^{\circ}$  F.:—

I.	115.0565
II.	114.7232
III.	114.9458
IV.	114.7318

---

Mean=114.8643

We deduce that a volume of paraffine=100 at 32° F. will be 7 at 142° F. in the fluid state; and if we subtract the volume between 32° and 142° F. of the solid, we find that the actual volume of the semisolid paraffine in passing into the perfect liquid will be the volume 100 at 32° taken as the starting-point.

*of the coefficient of expansion of liquid paraffine between 32° F. and its boiling-point (presumably about 750° F.).*

Paraffine was heated in tubes of known weight and capacity in a bath of oil, and the weight of paraffine which exuded between any two temperatures was determined. Specific-gravity flasks and stoppers were found to be unsuitable for the determination of the difficulty of uniformly heating the mass of liquid. Many attempts were made to determine the increase of volume with the temperature, but the results were not satisfac-

It is thus seen that paraffine is a body which undergoes a most unusual expansion in passing from its ordinary solid condition to the high boiling-

possesses. I do not remember any other substance of a kind which occupies at the boiling-point a volume which is nearly as large again as the volume at the ordinary temperature. In the accompanying figure (p. 115) I have introduced, side by side with the expansion curve, the expansion curves of mercury, iodide of silver, and phosphorus, one of the most expansible liquids known, if not of any bodies as ether, bromide of ethyl, acetate of methyl, &c., the boiling-point of which is below  $100^{\circ}\text{C}$ ., and which, therefore, could be introduced into the figure for comparison with a body which boils at  $400^{\circ}\text{C}$ .

Experiments showing the Paramagnetic condition of Arterial Blood as compared with the Diamagnetic condition of Venous Blood.

By RICHARD C. SHETTLE, M.D. Communicated to the Royal Society by LOCKHART CLARKE, F.R.S. Received October 20, 1874.

The condition of all matter has been well ascertained, and the same matter may exhibit different magnetic phenomena when placed in the medium in which it is placed is a point of considerable importance when testing for such results.

It is absolutely essential that any experiments which have

The thin glass vessel for holding the medium in which the testing-tube was suspended consisted of an ordinary beaker (fig. 2) of sufficient

Fig. 1.

Fig. 2.

internal capacity to allow of the testing-tube rotating freely, without risk of touching the sides. The mouth of this vessel was closed with a cork (fig. 3), the cork being pierced with two glass tubes, to which were

Fig. 3.

attached pieces of india-rubber tubing, capable of being closed when required by means of strong brass clips. This cork was also pierced in its centre by a small copper wire, bent into a crook at its lower end, to which the testing-tube was suspended. The wire was sufficiently long to permit of the testing-tube being raised or lowered as necessary for adjusting the ends to the level of the poles of the magnet.

The bottles used for defibrinating (fig. 4) were wide-mouthed, and capable of holding two pints each; they were well corked, and the corks were pierced with two glass tubes with india-rubber tubing attached, similar to the cork shown in fig. 3. Brass clips were also supplied. Into the under surface of these corks were driven four strips of wood sufficiently long to reach to the bottom of the bottle, and these acted as excellent defibrinating rods.

bottles (fig. 5) were narrow-mouthed, capable of holding a  
 e closed with a cork with one glass tube, fitted with india-

Fig. 4.

Fig. 5.

and, as the others. Near the bottom of these bottles

attached to the bottom of one of the store bottles, and then removing the clips, which were replaced as soon as the tube (fig. 1) was thoroughly filled: the open tube (*b*) was then speedily tied over with the thin india rubber; the india-rubber tubing connecting it with the store bottle was then carefully removed, and the aperture (*a*) tied over in the same manner; the tube was then carefully wiped and attached by the suspending silk to the crook of the adjusting-wire.

The tube (fig. 1) was first filled with arterial blood, and the vessel (fig. 2) having been filled with carbonic acid gas and placed between the poles of the passive electromagnet, the cork with testing-tube attached, filled as above described, was properly inserted; by means of the adjusting-wire (fig. 3) the points of the tube were made level with the points of the magnetic poles; battery contact was then made, and the tube (fig. 1) took up a diagonal position, pointing north-east by east and south-west by west. The tube connected with the bottom of the store bottle containing venous blood was now connected with one of the glass tubes of the vessel (fig. 2); and the clips being again removed, sufficient venous blood was allowed to run into it to cover the tube (fig. 1), with the exception of the two apertures covered with india rubber, as these marked the position of the tube when immersed in the blood. The tube immediately assumed the direct axial line, then slowly made a half turn and took the axial position again, the ends of the tube being directed to the poles of the magnet, the reverse of that they had first assumed.

#### *Experiment No. 2.*

The suspending-tube was now removed and thoroughly emptied of its contents. It was then filled with venous blood in the manner described in Experiment No. 1, and suspended as before, with the exception that the vessel (fig. 2) was this time filled with atmospheric air instead of carbonic acid gas; the tube was then levelled and tested by battery contact being made as in No. 1, and found to occupy an equatorial position. Arterial blood was then allowed to flow into fig. 2 from the store bottle in the same manner as described in Experiment No. 1; the slight oscillations which had previously existed immediately ceased, and the vessel (fig. 1) came to rest in the equatorial line.

#### *Observations.*

For the proper performance of these experiments special attention should be given,

1st, to the proper coagulation and removal of the fibrin;

2nd, to the preparation of the blood without contact with the atmosphere;

3rd, to the employment of sufficient battery force, not less than 15 Grove's cells.

1st. It is very necessary that the fibrin be properly removed, for the liquor sanguinis and corpuscles constitute together a medium of con-

*On the Multiplication of Definite Integrals.* [Dec. 10,

sity, in which the testing-tube has to rotate; and in calculating the degree of force which exists in the blood, as shown by the movements of the tube under the influence of the magnet, must be made for the resistance from this source that has to be overcome; consequently any fibrin that has not been removed must, in the degree in which it increases the viscosity and density of the blood, increase the resistance to the movements of the tube, and so interfere with the manifestation of results.

By preserving the blood from contact with the atmosphere any change of its physical character from such source is prevented.

For the reason that the paramagnetic force in arterial blood depends upon the amount of oxygen it contains, and the diamagnetic force in venous blood upon carbonic acid, it is evident that the force in the testing-tube as opposed to the force in the suspending medium is very little, whilst the mechanical resistance afforded by such a medium may be considerable. It is therefore essential that the battery should be of sufficient power to *develop* these forces to the greatest extent.

*Addendum.*

In writing the foregoing paper, in repeating the experiments, it has been found that, for the due performance of them, the blood should be kept at its natural temperature. The effect

and computing the integral as extended over an area bounded by the four straight lines thus represented, we have

$$\begin{aligned} \int_{y_0}^{y_1} \int_{x_0}^{x_1} P \, dx \, dy = & \int_{\frac{x_0+y_0}{\sqrt{2}}}^{\frac{x_0+y_1}{\sqrt{2}}} \int_{y_0, \sqrt{2}-\xi}^{\xi-x_0, \sqrt{2}} P \, d\eta \, d\xi + \int_{\frac{x_0+y_1}{\sqrt{2}}}^{\frac{x_1+y_0}{\sqrt{2}}} \int_{y_0, \sqrt{2}-\xi}^{y_1, \sqrt{2}-\xi} P \, d\eta \, d\xi \\ & + \int_{\frac{x_1+y_0}{\sqrt{2}}}^{\frac{x_1+y_1}{\sqrt{2}}} \int_{\xi-x_1, \sqrt{2}}^{y_1, \sqrt{2}-\xi} P \, d\eta \, d\xi. \end{aligned}$$

After I had discovered this formula, I found that it had been already given in a memoir by Dr. Winckler in the Vienna Transactions for 1862. This memoir treats of the transformation of double integrals between fixed limits, and seems to me one of great interest and importance. My present object is to give two formulæ for the multiplication of definite integrals which will not be found in Dr. Winckler's paper.

$$\begin{aligned} \int_{y_0}^{y_1} e^{y^2} dy \int_{x_0}^{x_1} e^{-x^2} dx = & \frac{e^{-x_0^2}}{2} \int_{y_0}^{y_1} \frac{e^{y^2} dy}{z+x_0} - \frac{e^{-x_1^2}}{2} \int_{y_0}^{y_1} \frac{e^{y^2} dy}{z+x_1} \\ & - \frac{e^{y_0^2}}{2} \int_{x_0}^{x_1} \frac{e^{-x^2} dx}{z+y_0} + \frac{e^{y_1^2}}{2} \int_{x_0}^{x_1} \frac{e^{-x^2} dx}{z+y_1}. \end{aligned}$$

Also

$$\begin{aligned} \int_{y_0}^{y_1} e^{y^2} dy \int_{x_0}^{x_1} e^{x^2} dx = & \frac{x_1 e^{x_1^2}}{2} \int_{y_0}^{y_1} \frac{dz \cdot e^{y^2}}{z^2+x_1^2} - \frac{x_0 e^{x_0^2}}{2} \int_{y_0}^{y_1} \frac{dz \cdot e^{y^2}}{z^2+x_0^2} \\ & + \frac{y_1 e^{y_1^2}}{2} \int_{x_0}^{x_1} \frac{dz \cdot e^{x^2}}{z^2+y_1^2} - \frac{y_0 e^{y_0^2}}{2} \int_{x_0}^{x_1} \frac{dz \cdot e^{x^2}}{z^2+y_0^2}. \end{aligned}$$

The use of these formulæ is easily seen.

December 17, 1874.

JOSEPH DALTON HOOKER, C.B., President, in the Chair.

The Presents received were laid on the table, and thanks ordered for them.

The following Papers and Communications were read:—

- I. "On Polishing the Specula of Reflecting Telescopes." By W. LASSELL, F.R.S., V.P.R.A.S. Received November 11, 1874.

(Abstract.)

The object of this paper is to describe a method of giving a high lustre and true parabolic curve with ease and certainty, by appropriate machinery, to the surfaces of the specula of large reflecting telescopes.

*Polishing the Specula of Reflecting Telescopes.* [Dec. 17]

It is remembered that many years ago Mr. Lassell invented, and published in the eighteenth volume of the *Memoirs of the Royal Astronomical Society*, a machine for polishing specula. It is no part of the object of this paper to disparage or supersede that machine, as with it have been polished many specula sensibly perfect, some of which are now in use, on, in whose surfaces he can find no imperfection whatever, which he should vainly attempt to improve; but it possesses scarcely sufficient strength for polishing a two-foot speculum, though the speculum of the telescope of that size which he took out to Malta in 1835 was polished with that machine. Indeed the first surfaces on the specula of the telescope taken out to Malta on his last expedition were obtained in the same way; but it was with great difficulty, and the machine broke down hopelessly, the result of which was the invention of the present one described in the paper now presented to the Society. But reference must be had to the paper itself, and to the plates which accompany it, for an adequate description.

In this machine there may possibly be found nothing very essentially new, it contains parts adopted from others and modified, the principal object being a method of giving a regular and gently controlled axial motion to the polisher while it is undergoing the various other motions of the machine.

The object of the present paper is to describe the processes with sufficient

through considerable changes of temperature, and renewing the surface for repeated polishings, are also described. The mode of construction of a bed of hones for bringing the curve of the speculum back to the sphere, if it should happen to have gone beyond the parabola in the polishing, without reverting to the emery-grinder, is also explained; and a word or two is added respecting the treatment of the speculum when finished.

II. "Note on the Vertical Distribution of Temperature in the Ocean." By J. Y. BUCHANAN, Chemist on board H.M.S. 'Challenger.' Communicated by Prof. A. W. WILLIAMSON, For. Sec. R.S. Received November 11, 1874.

From newspapers and other reports which have been received by late mails, it appears that the distribution of temperature in the ocean is occupying the attention of a certain portion of the scientific public, and even giving rise to considerable discussion. The observations made on board this ship, and more especially in the Atlantic, have furnished the greater part of the material on which the various speculations have been founded. It appears to me that one point suggested by these observations has not received sufficient attention from those who have written and spoken on the subject: I mean, the effect of the changing seasons on sea-water. Consider the state of the water at and near the surface of the ocean, somewhere not in the tropics. To be more precise, let us suppose that we have taken up our position in the middle of the North Atlantic, somewhere about the 30th parallel. This part of the ocean is not vexed with currents, and affords the best possible field for the observation of the phenomenon in question. The whole ocean enclosed by the 20th and 40th parallels of north latitude and the meridians of 30° and 60° west longitude forms one oceanic lake, not affected by the perturbing influence of currents or of land, and where, therefore, the true effect of differences of atmospheric temperature on the waters of the ocean may be most advantageously studied. Let us assume the winter temperature of the surface-water to be 60° F. and the summer temperature to be 70° F. If we start from midwinter, we find that, as summer approaches, the surface-water must get gradually warmer, and that the temperature of the layers below the surface must decrease at a very rapid rate, until the stratum of winter temperature, or 60° F., is reached; in the language of the isothermal charts, the isothermal line for degrees between 70° F. (if we suppose that we have arrived at midsummer) and 60° F. open out or increase their distance from each other as the depth increases. Let us now consider the conditions after the summer heat has begun to waver. During the whole period of heating, the water, from its increasing temperature, has been always becoming lighter, so that heat communication by convection with the water below has been entirely suspended during the whole period. The heating of

er has, however, had another effect, besides increasing  
as, by evaporation, rendered it denser than it was before,  
temperature. Keeping in view this double effect of the  
upon the surface-water, let us consider the effect of the  
on it. The superficial water having assumed the atmo-  
sphere of, say,  $60^{\circ}$  F., will sink through the warmer water  
it reaches the stratum of water having the same tempera-  
Arrived here, however, although it has the same tem-  
surrounding water, the two are no longer in equilibrium,  
which has come from the surface, has a greater density  
than the water at the same temperature. It will therefore not be  
a stratum of the same temperature, as would have been  
the case with fresh water; but it will continue to sink, carrying of course  
the lower temperature with it, and distributing it among the lower  
strata of water. At the end of the winter, therefore, and just  
before heating recommences, we shall have at the surface  
a thick stratum of water having a nearly uniform tempera-  
ture, and below this the temperature decreasing at a consider-  
able rate than at the termination of the summer heating.  
The difference between *surface-water*, the temperature of which rises  
with the atmospheric temperature (following thus, in direction at least,  
the seasons), and *subsurface water*, or the stratum imme-

carved) the slightly concentrated water descending from the surface as a winter approaches does not meet water of greater density at the same temperature than its own. Unfortunately the determination of the specific gravity of water below the surface is much less simple than that of the temperature; for although we have an instrument which gives, within any required degree of accuracy, the density of the water at any depth in exactly the same way as the thermometer gives its temperature, the results of the observations are composed of three factors, which depend on the temperature, the pressure, and the *salinity*. By sending down a thermometer along with it we might clear the result for temperature; by noting the depth we might clear for pressure; but the result so cleared would not represent the salinity of the water at the depth in question, but the average excess of salinity of the column of water above, over or under the mean salinity assumed for sea-water in the calculation of the pressure exercised by a column of it. There remains, therefore, nothing for it but to fetch a sample of water from each depth, and determine its specific gravity on board. As this is an operation which takes up some time, the number of "serial specific-gravity" determinations is comparatively small.

The following are the results of two which were obtained on the voyage between Bermuda and the Azores. The results show the specific gravity at 60° F., that of water at 39°·2 F. being taken as unity.

I. was taken on the 18th June, 1873, in lat. 35° 7' N., long. 52° 32' W.

II. was taken on the 24th June, 1873, in lat. 36° 3' N., long. 49° 19' W.

For comparison I give one equatorial and one South-Atlantic "serial specific-gravity" determination.

III. was taken on the 21st August, 1873, in lat. 3° 8' N., long. 4° 49' W.

IV. was taken on the 3rd October, 1873, in lat. 26° 15' S., long. 28° 56' W.

*Distribution of Temperature in the Ocean.* [Dec. 17,

figures in the Table it will be seen that in that part of the specific gravity of the water in summer decreases from the surface downwards. As a rule it attains an inferior limit at a depth of 500 fathoms, which it preserves to the bottom. In those places, therefore, the stratum of intermixture extends down to 500 fathoms; this may be said also to be the depth to which the sun's rays penetrate the surface penetrates. The results in column III. show the phenomenon of the surface-water being specifically lighter than the water below it, and that under an equatorial sun. The position of the stratum was peculiar, inasmuch as it was within line of separation between the Guinea and the equatorial currents. All along the equator the water at 50 and 100 fathoms was found to be specifically lighter than either at the surface or that at greater depths. All along the equator, however, a current runs with great velocity; and I have observed that strong surface-currents introduce considerable quantities of lighter water into the specific gravity of the water near the surface. The greater specific gravity at 100 fathoms conspires, of course with the small yearly range of temperature, in preventing vertical mixing in the above described manner. Column IV. shows a return from the Southern hemisphere to a state of things similar to that which obtains in the North Atlantic.

In the discussion of oceanic phenomena too much attention is usually paid to the great currents. When it is wished to study the phenomena due to temperature, or to any single cause, the effect of the winds, which is seen in its most intense form in the ocean-currents, should be eliminated as far as possible; which in this case can only be done by selecting comparatively motionless seas, like the one which I have mentioned in the North Atlantic\*. When the effect of atmospheric climate has been studied on the ocean at large, it would then be proper to apply the experience gained to the consideration of the more complicated phenomena of the currents.

I am at present engaged in a detailed consideration of the temperature and specific gravity results, principally in the direction above indicated, and hope shortly to be able to send it home for publication.

### III. "Preliminary Note upon the Brain and Skull of *Amphioxus lanceolatus*." By T. H. HUXLEY, Sec. R.S. Received December 17, 1874.

The singular little fish *Amphioxus lanceolatus* has been universally regarded as an extremely anomalous member of the Vertebrate series, by reason of the supposed absence of renal organs and of any proper skull and brain. On these grounds, chiefly, Agassiz proposed to separate it from all other fishes, and Haeckel, going further, made a distinct division of the Vertebrata (*Acrania*) for its reception; while Semper†, in a lately published paper, separates it from the Vertebrata altogether.

In a recent communication to the Linnean Society, I have described what I believe to be the representative of the ducts of the Wolffian bodies, or "primordial kidneys" of the higher Vertebrata, in *Amphioxus*; and I propose, in this preliminary notice, to point out that although *Amphioxus* has no completely differentiated brain or skull, yet it possesses very well-marked and relatively large divisions of the cerebro-spinal nervous axis and of the spinal column, which answer to the encephalon and the Cranium of the higher Vertebrata.

The oral aperture of *Amphioxus* is large, of a long oval shape, and

\* It will be seen that the principle that the depth to which the effect of the sun's rays penetrates depends on the yearly range of temperature of the water at the surface, explains the presence of the large body of comparatively warm water in the North Atlantic, the existence of which has been usually ascribed to an assumed reflux or back water of the Gulf-stream. The warm water is due to no extraneous cause, but is the natural effect of the conditions of climate at the surface; and the effect of these conditions of climate are so apparent in the temperature of the water, just because it is free from the influence of oceanic currents and exposed to the effects of climate alone.

† "Die Stammverwandtschaft der Wirbelthiere und Wirbellosen," Arbeiten aus dem zool.-oecol. Institut in Würzburg, Bd. ii. 1874, p. 42.

fringed by tentacles, external to which lies a lip, which is continuous behind with the ventro-lateral ridge of the body. The oral chamber is spacious, and extends back to the level of the junction between the sixth and seventh myotomes (fig. A). Here it is divided from the branchial cavity by a peculiarly constructed, muscular *velum palati*, the upper attachment of which to the ventral aspect of the sheath of the notochord lies vertically below the anterior angle of the seventh myotome.

Eight pairs of nerves are given off from the cerebro-spinal axis as far as this point. The eighth, or most posterior, of these, which, for convenience, may be called *h*, passes out between the sixth and seventh myotomes, and runs down parallel with the lateral attachment of the velum. The next five (*g, f, e, d, c*) pass out between the first six myotomes, and are distributed by their dorsal and ventral branches to those myotomes, to the integument, and to the walls of the buccal cavity. The foremost two nerves (*b* and *a*) pass in front of the first myotome, and the nerve *a* runs parallel with the upperside of the notochord to the end of the snout, giving off branches to that region of the body which lies in front of the mouth. This nerve lies above the eye-spot.

In the Marsipobranch fishes *Myrine* and *Ammocetes* (now known to be a young condition of *Petromyzon*) a velum also separates the buccal from the branchial cavity (figs. B, C, D). But this velum is in connexion with the hyoidean arch. The resemblance of the buccal cavity, with its tentacles, in *Ammocetes* to the corresponding cavity in *Amphioxus* is so close, that there can be no doubt that the two are homologous. In the *Ammocetes* there is a hyoidean cleft which has hitherto been overlooked. The auditory sac lies at the dorsal end of the arch and above the dorsal attachment of the velum. The latter, therefore, corresponds with the auditory region of the skull, and the nerve *h* should answer to the last of the præauditory cranial nerves, which is the *portio dura*. Assuming this to be the case, though the detailed homologies of the cranial nerves of the higher Vertebrata are yet to be worked out, it follows that the segment of the cerebro-spinal axis which in *Amphioxus* lies between the origin of the nerve *h* and the eye, answers to all that part of the brain which lies between the origin of the seventh nerve of *Petromyzon* and the optic nerve. Consequently, the lateral walls of the neural canal in the same region answer to that region of the skull in *Petromyzon* which lies between the origin of the seventh and the origin of the optic nerve. Hence, as each myotome of *Amphioxus* represents the corresponding portion of a protovertebra, it follows that the same region of the skull in the Lamprey and other Vertebrata represents, at fewest, six protovertebræ, almost all traces of which are lost, even in the embryo condition of the higher Vertebrata.

It may further be concluded that the several pairs of nerves which leave the cerebro-spinal axis, between those which answer to the *portio*

optic nerve, in *Amphioxus*, are represented by the third, and sixth pairs of cranial nerves of the higher Vertebrata. In fact, has the characteristic course and distribution of the ophthalmic division of the trigeminal; while, without at present being parallel, it is easy to see that the nerves *b, c, d, e, f*, and their respective myotomes, supply the requisite materials for the formation of the oculomotor, pathetic, trigeminal, and abducens muscles of the eye and of the jaws, in the more differentiated types.

The part of the cerebro-spinal axis of *Amphioxus* which lies between the seventh myotome answers to the præauditory part of the higher Vertebrata, and the corresponding part of the head to the auditory region of the skull in them. On the other hand, from the seventh myotome backwards, a certain number of segments answer to the auditory, or parachordal, region of the skull of the higher

Vertebrata. To the question, how many? involves sundry considerations. It must be recollected that though the branchial chamber of *Amphioxus* is the homologue of the branchial chamber of other Vertebrata, it does not necessarily follow that the imperfect branchial skeleton of *Amphioxus* corresponds with their branchial skeleton. The branchial

segment, it would appear that this segment is, in the main, the result of the chondrification, with or without subsequent ossification, of the fourteenth protovertebra.

There is no evidence, at present, that the ear-capsule represents a modification of any part of the vertebral skeleton, nor that the trabeculae are any thing but an anterior pair of visceral arches. And if these parts have nothing to do with centra, or arches, of vertebrae, it follows that the numerous protovertebrae, which lie in front of the fourteenth in *Amphioxus*, are represented only by muscles and nerves in the higher Vertebrata.

The anterior end of the cerebro-spinal axis of *Amphioxus* answers to the *lamina terminalis* of the thalamencephalon of the higher Vertebrata, the cerebral hemispheres and olfactory lobes remaining undeveloped.

If the auditory nerve is, as Gegenbaur has suggested, the dorsal branch of a single nerve which represents both the *portio dura* and the *portio mollis*, the auditory organ of *Amphioxus* is to be sought in connexion with the dorsal branch of its eighth nerve. I have found nothing representing an auditory organ in this position; and I can only conclude that *Amphioxus* really has no auditory apparatus. In all other respects, however, it conforms to the Vertebrate type; and, considering its resemblance to the early stages of *Petromyzon* described by Schulze, I can see no reason for removing it from the class Pisces. But its permanently segmented skull and its many other peculiarities suggest that it should be regarded as the type of a primary division or subclass of the class Pisces, to which the name of *Entomocrania* may be applied, in contrast to the rest, in which the primary segmentation of the skull is lost, and which may be termed *Holocrania*. On a future occasion I propose to show in what manner the skull of the Marsipobranch is related to that of the higher Vertebrata, and more especially to the skull of the Frog in its young tadpole state.

#### EXPLANATION OF THE FIGURES.

A, C, D are diagrammatic, but accurate, representations of the anterior part of the body in *Amphioxus* (A), in an *Ammocete* 1·6 inch long (C), and in a fully grown *Ammocete* 5·7 inches long (D). B is a copy of the furthest advanced stage of the young *Petromyzon planeri* six weeks after hatching, as figured by Schulze in his memoir on the development of that fish. The figures are magnified to the same vertical dimension, so as to afford a means of estimating, roughly, the changes in the proportional growth of the various parts of the head of the Lamprey in its progress from the embryonic towards the adult condition. In C, the brain is already differentiated into the three primary vesicles and the vesicles of the cerebral hemispheres, though they are not shown, the whole brain being merely indicated by the dark shading. The trabeculae (Tr), which have already united in front, are indicated, but not the semilunar ethmoidal cartilage, which lies above and behind the

in D, neither the ethmoidal nor the trabecular cartilages are shown, but of the brain is indicated; and the manner in which the longitudinal which represent the anterior myotomes of *Amphioxus*, are arranged in the tentacles of *Amphioxus* are represented by the tentacles of the hood-like "upper lip" of the latter obviously answering to the elongation of the head of *Amphioxus* with the two lateral folds of integument which lie outside the bases of the tentacles and are continued back into the lateral ridges. The relative shortening of the notochord, and lengthening of the region of the brain which lies in front of the origins of the optic nerves compared with B, is remarkable.

drawn in all the figures through the anterior margin of the nasal sac. Another has the same relation to the eyes (*Op-Op*); and a third passes through the region of the auditory sac and hyoidean arch. The hyoidean and first and second branchial clefts of *Ammocetes*, 1., 11. myotomes of *Amphioxus*; *My*, myelon or spinal cord; *Ch*, notochord.

received from the Naturalists attached to the Transit—  
of-Venus Expedition at Rodriguez.

Government House, Port Mathurin,  
Rodriguez, Nov. 2, 1874.

—I write to give you a short account of my proceedings  
hitherto so far in my explorations of the Rodriguez bone.

others might have entirely removed these. I found amongst these about thirty rings of the trachea or tracheæ.

Since then I have found a small hook in another cave, to which it was difficult, from the small size of the entrance, to penetrate. Into this also a slit or cleft from the surface had led, but had since been obliterated. In this I found, I should say, seven "sets" of bones of Solitaire. These were more or less mixed up together by the action of water; but they were still, to a certain extent, in groups, each group being those of an individual. Amongst these I found a perfect skull, with maxillæ attached, and the three parts of the mandible lying close by, four perfect and several injured furcula, and many rings of tracheæ.

I propose soon to try my fortune in a small marsh near here, which looks as if it might originally have been a lakelet or pond. I am induced to do so by the success that my labours met with in a similar locality in Mauritius. I have said "near here," but this is a slip of the pen; I should have said "near my encampment at the caverns."

I have found an immense quantity of tortoise-bones, from which I shall only make a selection before leaving. I have also exhumed a great quantity of bones of smaller birds; but I rather hesitate before giving a description of their genera.

I am afraid that I cannot send any bones by this mail, as the difficulty of transport is so very great. I have every week brought back a few bones of Solitaire, but have had hardly any time to put even these in gelatine, without which operation they would not travel with any degree of safety.

I am, dear Sir,

Very obediently yours,

To Prof. Huxley.

HENRY H. SLATER.

---

Rodriguez, Nov. 3, 1874.

MY DEAR SIR,—A mail being about to leave the island by H.M.S. 'Shearwater,' I now send you some account of my proceedings up to the present time.

I have searched for frogs, more especially tree-frogs, but all the natives of the island tell me that there are none; and as I have neither heard nor seen them, I conclude that this must be the case. With regard to lizards, there is a small house-lizard very abundant. It belongs to the genus *Peripia*, and is very probably the same as that found in Mauritius. It is not only found in houses, but also in trees, beneath the bark of which it lays its eggs. I have been told of a much larger lizard which inhabits a certain part of the island, and have myself searched the spot, but have been unable to find it. I have also offered a reward for a specimen, but have not yet procured one.

Letters from the Naturalists attached to [Dec. 17,

has been the case with regard to another lizard which lives  
and, a small island lying off the coast of Rodriguez.  
As to freshwater fish, there are said to be four kinds,

of perch, commonly called carp here.  
of eel, in most points agreeing with *Anguilla marmorata*,  
one important point at least. It undoubtedly enters the  
as the specimen which I have was caught about a quarter  
of the place whence we get our drinking-water.

of *Eleotris*, a specimen of which was caught at the same  
eel. This fish, however, undoubtedly enters brackish

of *Mugilus*. I have my doubts as to whether this fish  
called a freshwater species.

to the Arachnida, I have collected a considerable quantity  
have got specimens of the small scorpion which is very  
on the island.

opendra is very common; but a small species is not so, and  
succeeded in procuring one specimen.

ted a very considerable quantity of insects, more especially  
pleoptera.

have not been able to find, though I have made diligent

Rodriguez, November 1874.

SIR,—I send by the ‘Shearwater’ to-morrow, for transmission by the mail leaving Mauritius on the 12th instant, a packet of seeds of some of the plants of this island; and, in accordance with my instructions, I submit the following short report of my proceedings here up to the present date.

I have paid special attention to the Palms and *Pandani*. Of the former there are three species indigenous—one of the genus *Latania*, and two belonging to the genus *Areca*. The *Pandani* present much greater difficulty in their determination; and I do not yet feel in a position to fix definitely the number of species, although I rather incline to the idea that there are only two true species. My collection of the plants of the island now numbers about 450 species, of which about three fourths are Phænogams. I have made observations with the view of discriminating between the indigenous and introduced vegetation, but there are several plants regarding which I am doubtful. I have not yet succeeded in finding any marine Phænogams; hitherto, however, I have not devoted much time to the marine flora. There are no tree ferns on the island; at least I have seen none, and, as far as I can learn, none of the inhabitants have seen any. Ferns are represented by about two dozen species; mosses and freshwater algæ are not abundant, but lichens are very numerous, both as species and as individuals. This flora is by no means so extensive as I had expected; but the survey of the island just concluded by the officers of the ‘Shearwater’ shows the island is only about half the size it was previously supposed to be, it being only 11 miles long by 4 miles broad. The island is a volcanic one, consisting of a succession of lava-flows, radiating from one or more foci in the centre of the island, and now worn away so as to form a series of more or less parallel ridges, separated by deep ravines. These lava-flows are composed chiefly of a dark compact basalt, not unfrequently becoming porphyritic, and commonly exhibiting a marked columnar structure; and I have counted as many as twelve such flows, lying one above the other, separated severally, either by beds of conglomerate, or by beds of laterite, or variously coloured clayey beds. Granite and sandstone do not occur in the island. At the east and at the west ends of the island occur the only non-volcanic rock in the island, namely coralline limestone, extending in huge sheets over many acres of land, and also occurring in detached patches on the top of the basalt, often nearly a mile from the sea. On the northern and southern sides of the island it does not occur; but on the southern side may be seen some raised beaches, marking upheaval there, as does the coralline limestone at the east and west sides. Zeolites are common in the basalt in many places, as also several other minerals. The whole rocks of the island are permeated by iron. This report is very brief;

ricular systole at the heart and the closure of the aortic valve does vary when the pulse-rate is constant, and varies as the square root of length of the pulse-beat—being found from the equation  $xy=20\sqrt{x}$ , where  $x$ =the pulse-rate, and  $y$ =the ratio borne by the above-named part to whole beat.

This law, in a somewhat modified form, was enunciated by myself in a paper published in the 'Journal of Anatomy and Physiology' (vol. v. 1870), where the peculiarities of the curves taken in the lying posture led me as to the point of commencement of the ventricular systole, led me to state that posture had an effect on the duration of the pulse. Such, however, is not the case; for, while lying, the weight of the heart is apparently sufficiently great to neutralize the effect on the pulse of the auricular contraction, and to make the thus taken trace identical in the rise which at other times results from that contraction. In all events if this assumption be made, it is found that the lengths of different parts of the beat are not influenced by posture, and they agree exactly with the above-stated law.

The following are measurements made since the publication of the original paper, which tend fully to confirm the above statement:—

Pulse-rate.	Number of times the first part is contained in the whole beat.	Calculated ratio of first part to whole beat on formula $xy=20\sqrt{x}$ .

### Mr. A. H. Garrod on the

The length of the interval between the commencement of the pulse and the dicrotic rises in the radial artery is constant for any rate, and varies as the cube root of the length of the pulse. It is found from the equation  $xy' = 47\sqrt[3]{x}$ , where  $x$  = the pulse-length, and  $y'$  = the ratio borne by the above-named part to the whole beat. This was enunciated in the paper before referred to as read before me by myself, and published in its 'Proceedings' (vol. xviii). Since that paper was read a fresh series of measurements have confirmed its accuracy, and practice in manipulation has narrowed any limits of experimental error so far that a difference of more than 1 per cent from the calculated results is rarely found.

The following Table contains some of the more recent results and one or two careful measurements of old traces:—

Pulse-rate.	Ratio borne by sphygmocystole to whole beat, as	
	Found by measurement.	Calculated from equation $xy' = 47\sqrt[3]{x}$ (approximately).
38	4.175	4.18
43.5	3.825	3.8
44.5	3.7875	3.75
45	3.79	3.72

low the above law exactly, the following are the results obtained by measuring the carotid tracings :—

Pulse-rate.	Ratio borne by sphygmocystole to whole beat, as	
	Found by measurement.	Calculated from radial equation.
67	2·899	2·84
68	2·827, 2·6	2·8
72	2·7144	2·7
77	2·583	2·59
77	2·594	2·59

In another subject, ætat. 22, the following are the results :—

77	2·6625	2·595
78	2·575	2·575
85	2·443	2·44

With regard to the posterior tibial artery, most of the results were obtained by the employment of the double sphygmograph, to be described further on, in which the superposition of the simultaneous anterior tibial trace on that from the radial artery showed that the interval between the commencing primary and dicrotic rises is the same both. The following are a few independent measurements from tracings from the artery behind the ankle :—

Pulse-rate.	Proportion borne by first part to whole beat in ankle trace.	Proportion borne by first part to whole beat in radial trace (approximately).
70	2·7	2·76
73	2·675	2·685
80	2·596	2·525
82	2·4575	2·5
82·5	2·517	2·495
88	2·378	2·378

*Corollary.*—The length of the interval between the primary and secondary rises being exactly the same in the carotid, radial, and posterior tibial arteries, which are three vessels at very different distances from the heart, it is evident that the length of this interval is constant throughout the larger arteries, and must be of the same duration at the origin of the aorta that it is in the radial artery at the wrist.

Mr. A. H. Garrod on the

ry to Proposition III. leads to theoretical results of consequence; for as the duration of the different elements of the radial artery is the same as that in the commencing aorta, by superposing the sphygmograph-trace upon the cardiograph-trace, and knowing the pulse-rate, a comparison can be made between the duration of the physiological changes going on in the heart and those in the commencing aorta; in other words, the time during which the ventricular and arterial systoles are continuous can be ascertained with precision by an indirect method, which alone is possible in this subject.

From the equations given in Prop. I. and Prop. II., the length of the systole of each beat in the cardiograph- and sphygmograph-traces can be calculated with facility for any value of  $x$ . From the values above given, namely,  $xy=20\sqrt{x}$  and  $xy'=47\sqrt[3]{x}$ , it is found that the duration of the arterial systole is shorter than the cardiac, as was expected, because the cardiograph-trace is an indication of the tension of the muscular walls of the heart, and not of the contained blood; and because a certain tension must be reached by the intravascular blood at the commencement of the systole before it can push open the valves.

As the arterial systole being therefore shorter than the cardiac systole, it is evident that when an attempt is made to superpose them exactly

pulse-rate and becoming *nil* when it is 170 a minute, which may be fairly conceived to be very near the limit of cardiac rapidity in man.

That this interval (the *sypasis*) should vary so considerably in length with different pulse-rates is not easy to explain at first sight; nevertheless a careful review of the different processes which are in operation in the heart at the time has suggested to me an explanation which seems reasonable. It depends on the fact that the extreme shortness of the diastole makes any variation in its length have a marked influence on the amount of blood which enters the capillaries of the walls of the heart, and consequently influences the amount of work which the muscular fibres of the ventricle have to perform in emptying their interstitial vessels before they can commence contracting on the blood in their contained cavity. Experiment shows that the rapidity of the pulse does not depend on the pressure of the blood in the arterial system\*; consequently the length of the *sypasis* is not influenced by the arterial blood-pressure, which is the same thing as saying that the force of the cardiac contraction varies directly as the blood-pressure; for then the muscular power of the ventricular walls to overcome the intramural distention, varying with it, prevents its duration from being modified.

It has been my endeavour to show elsewhere† that the force of the heart's contraction is modified by the length of diastole, varying as its square root. Such being the case, it is evident that the length of the *sypasis* must vary with that of the diastole, though not to the extent that is found to occur. But the diastolic period being always so short, it is evident that the longer it is, the more thoroughly does the heart-tissue get permeated with blood, in a way which can have little or no influence on its nutritive power, but a great effect in modifying the length of the *sypasis* in the direction which is found to occur.

Again, referring to the results of the cardio-sphygmograph observations published by me in the 'Proceedings' of this Society (vol. xix. p. 318), that paper contains a Table of the length of the different cardio-arterial intervals; and if from the first cardio-arterial interval, as there defined, the length of the *sypasis* be subtracted at the corresponding rates, it will be found that the remainder of the interval is of exactly the same length as the second cardio-arterial interval, which, on the assumptions made, it could only be, as both the systole and the shock of the closure of the aortic valve are propagated along the arteries from the same point under similar circumstances. The following Table gives the lengths of the first cardio-arterial interval from which that of the *sypasis* as above determined has been subtracted, and by their side the lengths of the second cardio-arterial interval, as copied from the Table in the communication referred to; *their similarity cannot be the result of simple coincidence, as they are derived from independent sets of measurements.*

completion of the cardio-sphygmograph tracing above re-  
 as my endeavour to obtain satisfactory double sphygmo-  
 s from arteries at different distances from the heart. Two  
 successful attempts suggested the plan which has proved suc-  
 as soon evident that there is only one artery, other than the  
 it is possible to manipulate with any degree of facility,  
 on the experimenter is the subject of experiment. This  
 posterior tibial at the ankle, where it runs in the interval  
 internal malleolus and the tuberosity of the os calcis, just  
 off the internal calcaneal branches. On myself, this artery

ordinary sphygmograph, differs from that at the wrist in more than one point. The primary rise, as previously mentioned, is less abrupt; the following fall is more considerable, and is not broken by the notch nearly constantly seen in wrist traces of this rapidity. The secondary rise starts from a lower level and is well marked, reaching its climax considerably nearer the next primary rise than in the wrist trace. There is, however, another feature in the early part of the secondary rise in the ankle trace, which deserves special attention because of its general occurrence. As is well known, in wrist traces the secondary rise commences promptly and is quite uniform in character, but in ankle traces there is nearly always a short horizontal continuation of the curve immediately following the primary fall, the point of departure of the two lines being clearly indicated by an abrupt, though not considerable, change in direction. This horizontal portion of the trace is not of any considerable length, being in a pulse of 70 a minute about one eighth of the whole beat; it is followed by a well-defined secondary rise, which is much longer and more gradual than the primary. Though described above as horizontal, this short interval between the two undulations is not so always, being frequently slightly oblique, sometimes in one direction, sometimes in the other. When its curve is downwards (that is, when it tends in the same direction as the primary fall), it may appear to be part of that event, which would then look as if broken; when its curve is upwards (that is, when it tends in the same direction as the secondary rise), it makes the trace appear more normal in comparison with that from the wrist.

Having now explained the ankle sphygmograph-trace, in considering the simultaneous wrist and ankle traces it will be necessary to commence with the description of the instrument employed to obtain them. A drawing of it from above is seen in Plate 5. fig. 1, from the side in fig. 2, and a double sphygmogram is given in fig. 4.

*The double sphygmograph* is constructed from two of the ordinary sphygmographs of Marey, as first constructed by Breguet. One, that employed in taking the ankle trace, retains all its original parts, except the side lappets for fixing it to the arm, and its recording-apparatus receives the double trace. A second lever is fixed in connexion with it by two up-rights so placed as to allow the axis of the second lever to be parallel to and above the one belonging to the instrument, sufficient room being left to allow the latter to move unobstructed up to the top of the recording paper. This second lever, which is a *facsimile* of that used in the sphygmograph, is placed so that it will write on the same recording-paper as the first; but its position is reversed. The accompanying sketch (fig. 3) will show this point, it representing a side view of the ordinary knife-edge lever upside down—that is, with the surface (*s*) on which the knife-edge ought to slide uppermost. The object of this arrangement will be seen immediately.

The second sphygmograph has the watchwork removed, as well as the

Mr. A. H. Garrod on the

ch is fastened to the spring that presses on the pulse, to which a small wire loop is soldered. In addition, a small piece is screwed into the nearer of the two holes by which the watchwork is moved, in such a way that it can be made to revolve with difficulty. The two instruments are fastened together by means of a screw in the foot-sphygmograph, which binds a brass plate in that form. This screw is fixed on a plate of brass which is attached to the instrument furthest from the watchwork in the manner shown in Figure. The brass plate in the other sphygmograph, which is attached on the side of the body of the instrument close to the wrist-plate. The exact position of these additional pieces of brass is determined by the direction that a silk cord takes when, attached to the arbor-end of the inverted lever mentioned above, it is passed through the loop on the tip of the spring of the wrist-sphygmograph.

This cord has to be parallel to the sides of the ankle-sphygmograph, when the two instruments are fastened together with the binding-screws to one another.

In order to take a double trace, the nut is unscrewed, and the two instruments are separated from one another. The wrist-sphygmograph is bound, as usual, on the right arm. The silk cord attached to the arbor-end of the wrist-pulse lever (the upper one in the ankle-sphygmograph) is then threaded through the loop at the tip of the wrist-sphygmograph. The binding-screw to fix the two instruments is passed into

*Results arrived at from the study of the simultaneous wrist and ankle tracings.*

In employing the tracings obtained from the above compound instrument, two objects were kept in view—*first*, to find the interval between the commencement of the primary rises in the wrist and ankle curves; and *secondly*, to observe whether or no the superposition of the one trace upon the other verified or falsified the statement made in Prop. III., that the lengths of the different parts of each element of the curve were the same in the two arteries.

The following Table contains the measurements of the lengths of the intervals between the commencement of the primary rise in the wrist and ankle tracings at different rapidities of pulse, from which it is clear that this interval varies very slightly within the range that can be obtained, and that the tendency is for it to be very slightly longer in the slower pulses.

which gives an average length of ·0012314 of a minute for all the rates.

It being possible to estimate with considerable accuracy the distance from the aortic valves of the spots on the arteries at which the instrument is usually applied, it becomes a point of interest to determine from the facts arrived at the rapidity with which the primary undulation travels from its origin (the heart) to the peripheral vessels. The radial artery at the wrist and the posterior tibial artery at the ankle are, as nearly as can be determined, 29 inches and 52½ inches respectively from the origin of the aorta in myself (on whom all the tracings have been taken), as previously mentioned; and as the time of transit of the wave

varies very little with different rapidities of pulse, a single example may be taken to illustrate the point in question. With the heart beating 100 times in a minute, the time taken by the primary wave in reaching the wrist (that is, the length of the first cardio-radial interval with the *syspasis* subtracted) has been shown in a previous Table to be  $\cdot 0021875$  of a minute. Adding to this the interval between the radial and aortic primary rise at the same rapidity, which is very nearly  $\cdot 00116$  of a minute,  $\cdot 0033475$  of a minute is the time taken by the systolic wave in travelling from the heart to the ankle. But if this wave went the extra distance to the ankle,  $(52\cdot 5 - 29 =) 23\cdot 5$  inches, at the same rate at which it reaches the wrist, the length of the first cardio-malleolar interval would be  $\cdot 00459375$  of a minute ( $29 : 52\cdot 5 :: 21875 : 459375$ ); but it is only  $\cdot 0033475$  of a minute, which is considerably less; consequently the wave *augments in rapidity as it gets further from the heart*, a phenomenon beyond my power to explain.

By superimposing the wrist trace from a simultaneous sphygmogram on that from the ankle, it is found that the components of each are of exactly similar duration, though the peculiar short interval following the dirotic notch in the latter sometimes complicates the results. This exact similarity in length of the different elements of the two pulses is not, as will be found by those who attempt to measure them practically, so evident from the tracings themselves; because the one being slightly later than the other, and the watchwork varying in rapidity, gradually increasing and then declining, the radial, which is the earlier, is slightly the shorter in the commencement of the trace and the longer towards its end. In the middle of the recording-paper the two coincide. It may therefore be said that the compound sphygmograph-trace is entirely in favour of the correctness of Prop. III.

In conclusion, the following is a summary of the results arrived at in this communication:—

I. The lengths of the different elements of the pulse-beat being the same in arteries at different distances from the heart, the radial sphygmograph-trace expresses their duration in the aorta.

II. The cardiosystole being longer than the sphymosystole at all possible pulse-rates, the excess in the length of the former expresses the time required by the heart to reach, from a state of rest, a systolic pressure sufficient to open the semilunar valves. This interval, termed the *syspasis*, is constant for any given rapidity of cardiac action, and rapidly decreases as the pulse gets quicker, becoming *nil* at a rate of 170 a minute.

III. The interval between the commencement of the primary pulse-rise in the radial and that in the posterior tibial artery is less than would be estimated from the time taken by the same wave in travelling from the aortic valve to the radial artery.

The woodcut (p. 151) will assist in illustrating the mutual relations of the different component parts of the cardiac revolution, as its different elements are there shown in their actual relations one to the other.

Mr. A. H. Garrod on the

le with different rapidities of pulse, a single example may illustrate the point in question. With the heart beating 100 a minute, the time taken by the primary wave in reaching the wrist, the length of the first cardio-radial interval with the (corrected) has been shown in a previous Table to be  $\cdot 0021875$ . Adding to this the interval between the radial and ankle at the same rapidity, which is very nearly  $\cdot 00116$  of a minute,  $\cdot 75$  of a minute is the time taken by the systolic wave in reaching the heart to the ankle. But if this wave went the extra distance to the ankle,  $(52\cdot 5 - 29 =) 23\cdot 5$  inches, at the same rate at which it travels at the wrist, the length of the first cardio-malleolar interval would be  $\cdot 004375$  of a minute ( $29 : 52\cdot 5 :: 21875 : 459375$ ); but it is only  $\cdot 00116$  of a minute, which is considerably less; consequently *the wave travels more rapidly as it gets further from the heart*, a phenomenon beyond explanation.

Comparing the wrist trace from a simultaneous sphygmogram with the ankle, it is found that the components of each are of equal duration, though the peculiar short interval following the first wave in the latter sometimes complicates the results. This exact equality of the different elements of the two pulses is not, as is often supposed, those who attempt to measure them practically, self-evident in the tracings themselves; because the one being slightly later

The purification of the various metallic spectra has at present been only partially effected ; but I have seen enough already to convince me of the extreme rigour with which the principle I have already announced may be applied, while, at the same time, there are evidences that the application of it may lead to some results not anticipated in the first instance.

My object in laying these maps before the Society, and presenting this *ad interim* report of progress, is to appeal to some other man of science, if not in England, then in some other country, to come forward to aid in the work, which it is improbable that I, with my small observational means and limited time, can carry to a termination. I reckon that, having regard to routine solar work, it will require another year before the portion from H to G is completely finished, even for the metals the spectra of which are shown in the maps now exhibited. When this is done there will still remain outstanding all the ultra-violet portion, the portion from G to F (both capable of being photographed by short exposure), and the whole of the less-refrangible part (which both Draper and

have shown can be reached by long exposure with the  
(ses).

I think, moreover, that when the light which the spectro-  
scopy thrown upon molecular action shall be better known,  
basis for further inquiry, methods of photography greatly  
present one in rapidity, in the less-refrangible portion of  
will be developed and utilized in the research.

[Plate 8.]

s 1866, 1868, and 1871\* I had the honour to communi-  
val Society some observations with the spectroscope of five  
including Encke's comet at its return in 1871.

experiments showed that a great part of the light of these

bands and the faint continuous spectrum were observed to vary in relative intensity.

When the slit was brought back past the nucleus on to the commencement of the tail, the gaseous spectrum became rapidly fainter, until, at a short distance from the nucleus, the continuous spectrum predominated so strongly that the middle band only, which is the brightest, could be detected on it.

We have presented to us, therefore, by the light of the comet three spectra :—

1. The spectrum of bright bands.
2. The continuous spectrum of the nucleus.
3. The continuous spectrum which accompanies the gaseous spectrum in the coma, and which represents almost entirely the light of the tail.

#### *1. The Spectrum of Bright Bands.*

The three bright bands were obviously similar in position and character to those which were observed in Comet II., 1868. In that comet the bands could not be resolved into lines ; but in the spectrum of the comet now under observation, on some occasions, especially during the early part of July, the three bands were partially resolved into lines. The resolution of the bands was seen most distinctly at the boundary of the coma, where the continuous spectrum was very faint.

The bands appeared to me to be brighter relatively to the continuous spectrum during the early part of the time that the comet was under observation.

On July 7, the bands were compared directly with the spectrum of the induction-spark taken in a current of olefiant gas. I suspected a small shift of all three bands towards the more-refrangible end of the spectrum.

July 8.—I made some measures of the want of coincidence of the less-refrangible edge of the middle and brightest band with the corresponding part of the band in the spectrum of the blue part of a small oil-flame. Afterwards I found that the collimating lens had shifted during the taking of the measures. I repeated the observations on July 13. On this day I estimated the shift of the brightest band to be about  $\frac{1}{4}$  of the distance of  $b^2$  to  $b^3$ . The other bands appeared to be similarly displaced in relation to the bands of the terrestrial spectrum. The estimation of the amount of displacement was rendered more difficult by the circumstance that the cometary band was not so bright at the less-refrangible limit as was the band in the spectrum of the oil-flame. With this exception, the relative brightness of the different parts of the bands agreed with the corresponding parts of the bands in the terrestrial spectrum.

On the supposition of the identity of the comet's bands with those of the spectrum of carbon, the shift which was observed would indicate a

of approach of the comet and the earth of about 40  
second, a velocity nearly double that of their actual relative

to a table of the comet's motion, kindly furnished to me by  
R.S., the comet was approaching the earth on that day with  
about 24 miles per second. The part of the earth's orbital  
direction of the comet may be disregarded, as it was less  
per second.

going observations the slit was placed on the brightest part  
ne, close in front of the nucleus. Was any part of the  
the motion of the matter within the comet? If the mea-  
July 8, when the lens was found to have shifted, could  
trustworthy, they would indicate a slightly larger shift on

on with the question whether the bright bands were fur-  
pour containing carbon in some form, it is of importance  
the bright line near G which accompanies the three bands  
m of carbon and its compounds appears to be absent in the  
comet. I took some pains to satisfy myself that this line  
detected in the comet's spectrum. If it had been present  
the relative brilliancy which it possesses in the terrestrial  
ould have been able to see it easily. The relative faint-  
the absence of this more-refrangible band might find its  
possibly in the low temperature of the cometary matter.

s are to be considered as due to carbon, we have to inquire  
the carbon exists in the matter of the comet. In my paper  
1868, I pointed out that though some comets have been

obtained, together with the known lines of oxygen, when carbonic acid and carbonic oxide were employed.

## 2. *The Continuous Spectrum of the Nucleus.*

I was not able to satisfy myself of the existence in the continuous spectrum of the nucleus of any dark lines, nor of any bright lines, other than the three bright bands which have been described.

I found that the presence of the bright bands increased the relative brightness of the middle part of the linear continuous spectrum, so as to give an apparently smaller relative amplitude to the red and violet parts of the spectrum. This was particularly noticed to be the case during the first week of July. When some breadth was given to the spectrum by means of a cylindrical lens, the bright bands were clearly distinguished in it, and then the relative brightness of different parts of the continuous spectrum was more nearly that of an ordinary incandescent body. The blue end of the continuous spectrum appeared to fail abruptly a little beyond G, and I was not able to trace the spectrum beyond this point. I took this circumstance at first to show the absence of the violet rays, and consequently a low temperature in the nucleus. Afterwards, when the solar spectrum was reduced to about the brightness of that of the comet, I observed a similar apparent abrupt termination of light at the same part of the spectrum, which is therefore a phenomenon due to the eye of the observer. Although it is probable that the violet rays are absent, or at least not present with any great intensity in the light of the nucleus, this observation of the apparent failure of the spectrum a little beyond G cannot, by itself, be accepted as a trustworthy proof that such is really the case.

When the nucleus was examined in the telescope, it appeared as a well-defined minute point of light of great brilliancy. I suspected at times a sort of intermittent flashing in the bright point. The nucleus suggested to me an object on fire, of which the substance was not uniform in composition, so that at intervals it burned with a more vivid light. On July 6th the diameter of the nucleus, when measured with a power of 800, was 1".8. On July 13th the measure was nearly double, viz. 3"; but at this time the point of light was less defined. On July 15th the nucleus appeared elongated towards the following side of the comet, at an angle of about 40° to the comet's axis.

The nucleus appeared of an orange-colour. This may be due in part to the effect of contrast with the greenish light of the coma. Sir John Herschel described the head of the comet of 1811 to be of a greenish or bluish-green colour, while the central point appeared to be of a pale ruddy tint. The elder Struve's representations of Halley's comet, at its appearance in 1835, are coloured green, and the nucleus is coloured reddish yellow. He describes the nucleus on October 9 thus, "Der Kern zeigte sich wie eine kleine, etwas ins gelbliche spielende, glühende Kohle von länglicher Form." Dr. Winnecke describes similar colours in the bright

, as it was seen on a background of sky illuminated by the lights of London; and as it approached the horizon, it became partially concealed by the chimneys of some neighbouring houses. Nearly the whole of the time that the comet was visible was consumed in the observations with the heliometer; and a few sketches only were made of the appearances presented by the head of the comet in the telescope.

Two sketches which accompany this note (Plate 6) were made on the 13th and 14th. On the latter evening the fainter parts of the coma, which were wanting in the sketch, were rendered invisible by the bright light of the sky. Two of the phases presented by the intersection of the envelopes are shown in the sketches. The narrow black channel by which the nucleus passed on the right-hand side of the nucleus (as seen in the telescope), where it terminated in a small round extension, presented something of the appearance of a black pin, with its head by the side of the nucleus.

**"On Acoustic Reversibility."** By J. TYNDALL, D.C.L., LL.D., F.R.S. Received December 31, 1874.

On the 21st and 22nd of June, 1822, a Commission appointed by the Academy of Longitudes of France executed a celebrated series of experiments on the velocity of sound. Two stations had been chosen, the one at Villejuif, the other at Montlhéry, both lying south of Paris, and 11·6 miles distant from each other. Prony, Mathieu, and Arago were the observers at Villejuif, while Humboldt, Bouvard, and Gay-Lussac were at Montlhéry. Guns, charged sometimes with 2 lbs. and sometimes with 4 lbs. of powder, were fired at both stations, and the velocity was deduced

Prof. J. Tyndall on *Acoustic Reversibility*. [Jan. 7,

ognized as the cause of the observed difference ; but the air is calm, the slight motion of translation actually existing from Villejuif towards Montlhéry, or against the direction in which the sound is best heard.

It was the difference in transmissive power between the two stations. On the 22nd of June, while every shot fired at Montlhéry was "heard" at Villejuif, but one shot out of twelve fired at Villejuif was heard, and that feebly, at the other station.

The explanation which characterized him on other occasions, and which was referred to admiringly by Faraday\*, Arago made no attempt to solve the anomaly. His words are :—"Quant aux différences si remarquables d'intensité que le bruit du canon a toujours présentées dans la propagation du nord au sud entre Villejuif et Montlhéry, et du sud au nord entre cette seconde station et la première ; nous ne sommes pas aujourd'hui à l'expliquer, parce que nous ne pourrions proposer que des conjectures dénuées de preuves" †.

He then proceeded, after much perplexity of thought, to bring this subject within the range of experiment, and have now to submit to the world a possible solution of the enigma. The first step was to determine whether the sensitive flame referred to in my recent paper in the *Philosophical Transactions* could be safely employed in experiments on the mutual reversibility of a source of sound and a receiver to which the sound impinges. Now the sensitive flame

or the orifice to the end of the tube, the flame was violently agitated by the sounding-reed, R. On shifting the tube, or the burner, so as to concentrate the sound on a portion of the flame about half an

Fig. 1.

inch above the orifice, the action was *nil*. Concentrating the sound upon the burner itself about half an inch below its orifice, there was no action.

These experiments demonstrate the localization of "the seat of sensitiveness," and they prove the flame to be an appropriate instrument for the contemplated experiments on reversibility.

The experiments proceeded thus:—The sensitive flame being placed close behind a screen of cardboard 18 inches high by 12 inches wide, a vibrating reed, standing at the same height as the root of the flame, was placed at a distance of 6 feet on the other side of the screen. The sound of the reed, in this position, produced a strong agitation of the flame.

The whole upper half of the flame was here visible from the reed; hence the necessity of the foregoing experiments to prove the action of the sound on the upper portion of the flame to be *nil*, and that the waves had really to bend round the edge of the screen so as to reach the seat of sensitiveness in the neighbourhood of the burner.

The positions of the flame and reed were reversed, the latter being now close behind the screen, and the former at a distance of 6 feet from it. The sonorous vibrations were without sensible action upon the flame.

The experiment was repeated and varied in many ways. Screens of various sizes were employed; and instead of reversing the positions of the flame and reed, the screen was moved so as to bring, in some experiments the flame, and in other experiments the reed, close behind it. Care was also taken that no reflected sound from the walls or ceiling of the laboratory, or from the body of the experimenter, should have any thing to do with the effect. In all cases it was shown that the sound was effective when the reed was at a distance from the screen and the flame close

while the action was insensible when these positions were

fig. 2, be a vertical section of the screen. When the reed  
the flame at B there was no action; when the reed was at B

Fig. 2.

at A the action was decided. It may be added that the  
communicated to the screen itself, and from it to the air beyond  
out effect; for when the reed, which at B is effectual, was  
where its action on the screen was greatly augmented, it  
any action on the flame at A.

w, I think, prepared to consider the failure of reversibility  
experiments of 1822. Happily an incidental observation of  
nce comes here to our aid. It was observed and recorded  
at while the reports of the guns at Villejuif were without

strong reason to question the hypothesis of the illustrious French philosopher.

And considering the hundreds of shots fired at the South Foreland with the attention specially directed to the aerial echoes, when no such case occurred in which echoes of measurable duration did not accompany the report of the gun, I think Arago's statement that at Villejuif echoes were heard when the sky was clear must simply mean that they vanished with great rapidity. Unless the attention were specially directed to the point, a slight prolongation of the cannon-sound might well escape observation; and it would be all the more likely to do so if the echoes were so loud and prompt as to form apparently part and parcel of the direct sound.

I should be very loth to transgress here the limits of fair criticism and to throw doubt, without good reason, on the recorded observations of an eminent man. Still, taking into account what has been just stated, remembering that the minds of Arago and his colleagues were occupied by a totally different problem (that the echoes were an incident rather than an object of observation), I think we may justly consider the sound which he called "instantaneous" as one whose aerial echoes did not differentiate themselves from the direct sound by any noticeable fall of intensity, and which rapidly died into silence.

Turning now to the observations at Montlhéry, we are struck by the extraordinary duration of the echoes heard at that station. At the South Foreland the charge habitually fired was equal to the largest of those employed by the French philosophers; but on no occasion did the gun-sounds produce echoes approaching to 20 or 25 seconds' duration. They rarely reached half this amount. Even the syren-echoes, which were more remarkable and more long-continued than those of the gun, never reached the duration of the Montlhéry echoes. The nearest approach to it was on the 17th of October, 1873, when the syren-echoes required 15 seconds to subside into silence.

On this same day, moreover (and this is a point of marked significance), the transmitted sound reached its maximum range, the gun-sounds being heard at the Quenocs buoy, which is  $16\frac{1}{2}$  nautical miles from the South Foreland. I have already stated that the duration of the air-echoes indicates "the atmospheric depths" from which they come. An optical analogy may help us here. Let light fall upon chalk. The light is wholly scattered by the superficial particles; let the chalk be powdered and mixed with water, light reaches the observer from a greater depth of the turbid liquid. The solid chalk typifies the action of exceedingly dense acoustic clouds; the chalk and water that of clouds of moderate density. In the one case we have echoes of short, in the other of long duration. These considerations prepare us for the inference that Montlhéry, on the occasion referred to, must have been

\* Phil. Trans. 1874, pt. i. p. 202.

Prof. J. Tyndall on *Acoustic Reversibility*. [Jan. 7,

highly diacoustic atmosphere ; while the shortness of the  
gunf shows the atmosphere surrounding that station to  
be acoustically opaque.

any clue to the cause of the opacity ? I think we have.  
to Paris, and over it, with the observed light wind, was  
the air from the city. Thousands of chimneys to windward  
were discharging their heated currents ; so that an atmosphere  
of smoke in a high degree must have surrounded that station.  
At such a height in the atmosphere the equilibrium of temperature  
was destroyed. The non-homogeneous air surrounding Villejnif  
was typified by our screen with the source of sound close  
to the upper edge of the screen representing the place where  
the temperature was established in the atmosphere above the  
screen. In consequence of its proximity to the screen, the echoes from our  
source would, in the case here supposed, so blend with the direct  
sound as to be practically indistinguishable from it, as the echoes at Vil-  
lejnif blended with the direct sound so hotly, and vanished so rapidly, that  
they were not observed. And as our sensitive flame, at a distance,  
was not affected by the sounding body placed close behind the card-  
board, I take it, did the observers at Monthéry fail to hear  
the Villejnif gun. This is the explanation of Arago's dif-  
ficulty. I have the honour to submit to the Royal Society.

as to form an acute angle with each other. At the end of one is the vibrating reed  $r$ ; opposite the end of the other, and in the prolongation of  $PO$ , is the sensitive flame  $f$ , a second sensitive flame ( $f'$ ) being placed in the continuation of the axis of  $MN$ . On sounding the reed, the direct sound through  $MN$  agitates the flame  $f'$ . Introducing the square of calico  $ab$  at the proper angle, a slight decrease of the action on  $f'$  is noticed, and the feeble echo from  $ab$  produces a barely perceptible agitation of the flame  $f$ . Adding another square,  $cd$ , the sound transmitted by  $ab$  impinges on  $cd$ ; it is partially echoed, returns through  $ab$ , passes along  $PO$ , and still further agitates the flame  $f$ . Adding a third square,  $ef$ , the reflected sound is still further augmented, every accession to the echo being accompanied by a corresponding withdrawal of the vibrations from  $f'$  and a consequent stilling of that flame.

With thinner calico or cambric it would require a greater number of layers to intercept the entire sound; hence with such cambric we should have echoes returned from a greater distance, and therefore of greater duration. Eight layers of the calico employed in these experiments, stretched on a wire frame and placed close together as a kind of pad, may be taken to represent a very dense acoustic cloud. Such a pad, placed at the proper angle beyond  $N$ , cuts off the sound, which in its absence reaches  $f'$ , almost as effectually as an impervious solid plate\*: the flame  $f'$  is thereby stilled, while  $f$  is far more powerfully agitated than by the reflection from a single layer. With the source of sound close at hand, the echoes from such a pad would be of insensible duration. Thus close at hand do I suppose the acoustic clouds surrounding Villejuif to have been, a similar shortness of echo being the consequence.

A further step is here taken in the illustration of the analogy between light and sound. Our pad acts chiefly by internal reflection. The sound from the reed is a composite one, made up of partial sounds differing in pitch. If these sounds be ejected from the pad in their pristine proportions, the pad is acoustically *white*; if they return with their proportions altered, the pad is acoustically *coloured*.

In these experiments my assistant, Mr. Cottrell, has rendered me material assistance.

\* January 13th.—Since this was written I have sent the sound through fifteen layers of calico, and echoed it back through the same layers, in strength sufficient to agitate the flame. Thirty layers were here crossed by the sound.

Class of Identical Relations in the Theory of Elliptic  
ns." By J. W. L. GLAISHER, M.A., Fellow of Trinity  
Cambridge. Communicated by JAMES GLAISHER,  
Received November 23, 1874.

(Abstract.)

of the memoir is to notice certain forms into which the  
c functions admit of being thrown, and to discuss the iden-  
to which they give rise. These latter, it is shown, can be  
tly by the aid of Fourier's theorem, or in a less straight-  
er by ordinary algebra.

., consider the cosine-amplitude : it is shown that we have

$$K' r = \frac{\pi}{k K'} \left\{ \frac{1}{r^x + r^{-x}} - \frac{1}{r^{x-1} + r^{-(x-1)}} - \frac{1}{r^{x+1} + r^{-(x+1)}} \right\}$$

( $\phi$  even and  $\psi$  uneven) give rise to identities of the same class as (1), and which, it appears, are all elliptic-function relations. It is also pointed out how (1) and the other similar identities discussed in the memoir admit of being simply established by ordinary algebra and trigonometry in two different ways.

Other identities and formulæ are noticed and compared; *ex. gr.*, for the cosine-amplitude, writing

$$x = \frac{\pi u}{2K}, \quad z = \frac{\pi v}{2K'}, \quad q = e^{-\frac{\pi K'}{K}} = e^{-\mu}, \quad r = e^{-\frac{\pi K}{K'}} = e^{-\nu},$$

we have

$$\begin{aligned} \cos am u &= \frac{2\pi}{kK} \left\{ \frac{q^{\frac{1}{2}}}{1+q} \cos x + \frac{q^{\frac{3}{2}}}{1+q^3} \cos 3x + \frac{q^{\frac{5}{2}}}{1+q^5} \cos 5x + \&c. \right\} \\ &= \frac{2\pi}{kK} \cos x \left\{ \frac{q^{\frac{1}{2}}(1-q)}{1-2q \cos 2x + q^2} - \frac{q^{\frac{3}{2}}(1-q^3)}{1-2q^3 \cos 2x + q^6} + \&c. \right\} \\ &= \frac{\pi}{2kK'} \{ \operatorname{sech} z - \operatorname{sech}(z-\nu) - \operatorname{sech}(z+\nu) + \&c. \} \\ &= \frac{\pi}{2kK'} \left\{ \operatorname{sech} z - 4 \cosh x \left( \frac{\cosh \nu}{\cosh 2z + \cosh 2\nu} \right. \right. \\ &\quad \left. \left. - \frac{\cosh 2\nu}{\cosh 4z + \cosh 4\nu} + \&c. \right) \right\} \\ &= \frac{\pi}{kK'} \left\{ \frac{\sinh(\frac{1}{2}\nu - z)}{\cosh \frac{1}{2}\nu} - \frac{\sinh 3(\frac{1}{2}\nu - z)}{\cosh \frac{3}{2}\nu} + \frac{\sinh 5(\frac{1}{2}\nu - z)}{\cosh \frac{5}{2}\nu} - \&c. \right\} \\ &= \frac{\pi}{2kK'} \left\{ \operatorname{sech} z - \frac{4r}{1+r} \cosh z + \frac{4r^3}{1+r^3} \cosh 3z - \&c. \right\}; \end{aligned}$$

so that if  $x, z, \mu, \nu$  be any four quantities subject to the relations

$$\mu\nu = \pi^2, \quad z = \frac{\pi x}{\mu} \left( \text{so that } x = \frac{\pi z}{\nu} \right),$$

the identities are

$$\begin{aligned} &\operatorname{sech} x - \operatorname{sech}(x-\mu) - \operatorname{sech}(x+\mu) + \operatorname{sech}(x-2\mu) \\ &\quad + \operatorname{sech}(x+2\mu) - \&c. \\ &= \operatorname{sech} x - 4 \cosh x \left( \frac{\cosh \mu}{\cosh 2x + \cosh 2\mu} - \frac{\cosh 2\mu}{\cosh 4x + \cosh 4\mu} + \&c. \right) \\ &= 2 \left\{ \frac{\sinh(\frac{1}{2}\mu - x)}{\cosh \frac{1}{2}\mu} - \frac{\sinh 3(\frac{1}{2}\mu - x)}{\cosh \frac{3}{2}\mu} \right. \\ &\quad \left. + \frac{\sinh 5(\frac{1}{2}\mu - x)}{\cosh \frac{5}{2}\mu} - \&c. \right\} \dots \dots \dots (2) \\ &= \operatorname{sech} x - \frac{4 \cosh x}{e^{\mu} + 1} + \frac{4 \cosh 3x}{e^{3\mu} + 1} - \&c. \\ &= \frac{2\pi}{\mu} \left\{ \frac{\cosh z}{\cosh \frac{1}{2}\nu} + \frac{\cosh 3z}{\cosh \frac{3}{2}\nu} + \frac{\cosh 5z}{\cosh \frac{5}{2}\nu} + \&c. \right\} \\ &= \frac{2\pi}{\mu} \cos z \left\{ \frac{\sinh \frac{1}{2}\nu}{\sin^2 x + \sinh^2 \frac{1}{2}\nu} - \frac{\sinh \frac{3}{2}\nu}{\sin^2 x + \sinh^2 \frac{3}{2}\nu} + \&c. \right\} \end{aligned}$$

Mr. W. H. Johnson *on the Action of* [Jan. 14,

h, 'Die Lehre von den elliptischen Integralen,' 1864,  
(2),  $x$  must be less than  $\mu$ .

Formulae obtained in the memoir,

$$\tanh(x-\mu) + \tanh(x+\mu) + \&c.$$

$$= \frac{2x}{\mu} + \frac{2\pi}{\mu} \left\{ \frac{\sin 2z}{\sinh \nu} + \frac{\sin 4z}{\sinh 2\nu} + \&c. \right\},$$

$$\coth(x-\mu) + \coth(x+\mu) + \&c.$$

$$= \frac{2x}{\mu} + \frac{\pi}{\mu} \left\{ \cot z + \frac{4 \sin 2z}{e^{2\nu} - 1} + \frac{4 \sin 4z}{e^{4\nu} - 1} + \&c., \right.$$

On the remarkable Changes produced in Iron and Steel  
by the "Action of Hydrogen and Acids." By WILLIAM H.  
JOHNSON, B.Sc. Communicated by Prof. Sir WILLIAM THOMSON,  
F.R.S. Received December 7, 1874.

Years ago my attention was called to a remarkable change  
in the properties of iron caused by the treatment of iron

copious bubbles of gas being given off from the whole surface of the fracture for 30 to 40 seconds, or even longer, making the water on the fractured surface appear to boil violently. This frothing is increased by any thing that augments the heat produced by fracture; in fact it is necessary that the fracture be more or less warm to cause the escape of bubbles; for if the wire be nicked and broken short without generating any heat, few or no bubbles will be seen. By further experiment I found that other acids, such as acetic, had the same effect on iron as those first used; and it became evident that any acid which liberates hydrogen by its action on iron is able to produce them. Nitric acid, which under usual conditions does not liberate hydrogen by its action on iron, is, however, without effect. The frothing, the diminution of toughness, and all other changes caused by immersion in acid are, as a rule, only temporary; for after an exposure to a temperature of about  $16^{\circ}$  C. for three days, or of  $200^{\circ}$  C. for half a day, the wire will be found to have regained its original toughness, and no bubbles, or any sign of evolution of gas, will be seen, as before, on moistening the fracture. The bubbles also cease to be visible long before the wire has recovered its original toughness or elasticity. Immersion in water, particularly if warm, hastens the restoration of toughness, and numerous bubbles may be seen to arise from the iron when first immersed. If a little caustic soda, or other alkali, be added to the water in which the iron is laid, its recovery is still further hastened, as it neutralizes a film of acid which seems to adhere to the surface of all iron which has been attacked by acid.

It seems at first remarkable that steel does not froth when fractured after immersion in acid, under the same conditions as will produce a violent evolution of gas with iron; and yet the action of acids on steel is more rapid, more marked, and more permanent than on iron. The decrease in toughness is such that a piece of steel which, previous to immersion in hydrochloric or sulphuric acid, would stand bending on itself and back two or three times, will break short off like a pipe-stem when bent. So great is the influence of acid, in fact, that 10 minutes' immersion in dilute sulphuric acid will sometimes cause a coil of highly carbonized tempered cast-steel wire to break of itself into several pieces while in the liquid.

The amount of carbon in the steel appears, moreover, to be connected with the action of acid; for in mild Bessemer steels, containing about 0.20 to 0.25 per cent. of carbon, the change is a very little more marked than in iron, even frothing being apparent after prolonged immersion. With an increased percentage of carbon the action, however, is more marked and of longer duration. Half an hour's immersion in hydrochloric acid will make a piece of steel containing, say, 0.60 per cent. of carbon break with a much darker-coloured fracture, and render it so brittle that no amount of exposure to the air or heat will ever completely restore it. On hardened and tempered steel the decrease in toughness

immersion in acid is greater and more rapid than with the soft state.

That the absence of frothing on the surface of steel after acid might arise from the bubbles of gas given off being invisible to the naked eye, I examined the moistened piece of steel under a microscope with a power of 250 diameters. Expectations were fulfilled, for numbers of minute bubbles arise from parts of the moistened fracture. It appears that the open structure of iron allows any gas which has been a substance to pass more easily to the surface of the fracture than the close, unfibrous, homogeneous structure of steel; consequently the evolution of gas will not be so rapid with steel as with iron. The fracture of steel presents an almost infinite number of small openings favourable to the rapid evolution of small bubbles invisible to the naked eye. Iron wire, on the other hand, breaks with a fibrous fracture, which will retain the small bubbles until they have grown large enough to be visible to the naked eye. Hence the frothing in the fracture of steel.

Some experiments were made to ascertain if there was any increase in weight in iron which frothed over the same iron in the same state. The pieces of iron and steel wire, after immersion, were well washed in cold water, and when dry weighed, this was done when the metal contained the gas. Subsequently they

upon iron and steel, we will now more closely consider them with the object of discovering the cause.

It might at first sight be thought that the frothing could be explained on the supposition that by the action of acid, iron is thrown into what may be called the "active state," in opposition to the so-called passive state caused by nitric acid, and that in this "active state" it is able to decompose water at the ordinary temperature, forming oxide of iron and bubbles of free hydrogen. The facts, however, do not bear out this theory, as the bubbles are still seen if oil be employed instead of water; and no matter how numerous the bubbles, the closest examination fails to show any formation of oxide. Again, the frothing is greater from the long end than from the short end of the piece of wire, whereas, if due to oxidation, it should be the same at both ends.

Now the following facts make it certain that hydrogen is either the sole cause of the changes produced in iron by some acids, or is inseparably connected therewith:—

1st. Only those acids which evolve hydrogen by their action on iron produce any change in iron and steel, nitric acid (which does not liberate hydrogen except under particular conditions) having no effect.

2nd. It is difficult to collect the bubbles which form the froth on the moistened fracture of a piece of iron in sufficient quantity for analysis; but by putting a coil of wire, previously steeped in acid, into hot water under a bell-jar, the bubbles of gas evolved by the iron may be collected, and will be found to burn with the characteristic flame of hydrogen.

Hence it is probable that iron and steel, when placed in hydrochloric, sulphuric, or other acid, absorb some of the nascent hydrogen generated by the action of the acid, thus forming what, for lack of a better term, may be called an alloy\* of iron and hydrogen. This alloy may be compared to that formed when zinc is amalgamated with mercury; and just as in process of time the mercury disconnects itself from the zinc, appearing in globules on its surface, so hydrogen gradually disengages itself from the iron—a movement which is greatly facilitated by heat, as is natural to expect.

The analogy may be carried still further; for as amalgamated zinc is made brittle in consequence of the pores or interstices between the molecules of the metal being filled up by mercury, motion of one molecule over another being then impeded, so in like manner iron becomes brittle when its pores are filled up by condensed hydrogen gas; and naturally, when the hydrogen or mercury is driven out of the molecular interspaces, movement of the molecules on one another is less impeded, and hence the former toughness or elasticity is restored.

Nor is amalgamated zinc the only analogous case; for the following remarkable experiment lends further probability to the theory, by showing how rapidly the absorption of zinc by iron may take place, attended

\* By the term alloy I mean a solution of one metal in another.

results, as regards increased brittleness, to those which absorption of hydrogen. It also shows how rapidly, by a of temperature, zinc may be disengaged from the iron, it to regain its former toughness.

galvanized iron wire, of good quality, such that when cold it several times on itself and back again before breaking, was heat so quickly that the coating of zinc was melted and only vaporized. On attempting to bend it whilst still red-hot, it snapped, offering very little resistance to fracture. The fracture was of a blue-grey colour, as though the zinc had penetrated into the iron. When cold, the same piece broke with all its strength and with a long fibrous fracture. The wire was again heated so that the coating of zinc was completely vaporized, and then it was so tough that it was impossible to break at a red heat. Wire galvanized in zinc will often break short, though the part out of the acid is quite tough.

It is probable that this experiment will not succeed with all kinds of iron, not being made thus "red short" by zinc.

Testing the theory that occluded hydrogen is the cause of the properties of iron after its immersion in acids, the author has tried to dispense with acid altogether, and endeavour to produce the same result by subjecting pieces of iron to the action of nascent

the wire connected with the zinc pole of the battery was found to bubble. Twenty-two hours' longer immersion, the battery working all the time, caused the bubbles to be more abundant; the toughness of the wire was also diminished and its surface blackened. The wire at the positive pole was, however, unchanged, either on the surface or in toughness".\*

From this we see that not only is acid not indispensable for the production of, at all events, the major portion of these changes in iron, but the latter can be equally well produced in an alkaline solution.

The apparatus remaining unchanged, the soda was next replaced by hydrochloric acid, 1.20 sp. gr. On then immersing the iron-wire electrodes for only 2 or 3 seconds, the negative electrode, where hydrogen was given off, was found to froth freely when the fractured extremity was wetted, as much, in fact, as after 15 minutes' immersion when the current was broken. Half an hour's immersion failed to produce any similar change on the positive electrode where no hydrogen was liberated. The absence of effect on the positive electrode is all the more remarkable, as a piece of wire of exactly the same quality, and immersed an equal time in the same liquid, but unconnected with the battery, had become brittle and frothed when broken. It thus appears that neither oxygen nor chlorine are, under these conditions, occluded by iron, or if occluded, that they produce no sensible change in its physical properties.

Nascent hydrogen having been shown to produce these effects, a trial was next made to ascertain if any similar change could be produced in iron by leaving it in an atmosphere of hydrogen gas. With this object a glass tube  $\frac{1}{2}$ " in diameter was filled with pieces of bright iron wire  $\frac{1}{16}$ " in diameter, and a current of hydrogen passed through for periods of 1, 2, and 8 hours respectively, but without any perceptible change in the wire. The wires were then placed in a bottle three fourths full of water, and hydrogen made to bubble violently through the water for an hour, but still without any effect. It would thus appear that hydrogen is only occluded in the nascent state by iron in the cold. Possibly, however, absorption may take place if the surfaces are chemically clean. The late Dr. Graham, in his valuable papers on the occlusion of hydrogen, showed, several years ago, that when red-hot iron, palladium, or platinum are allowed to cool in an atmosphere of hydrogen, this gas is occluded by them in large quantity; and in the 'Proceedings of the Royal Society,' 1868, xvi. p. 422, he mentions that the best way of charging any of these metals with hydrogen is to make the metal act as the negative electrode in acidulated water for a battery of 6 Bunsen's cells—a fact unknown to the writer when he made experiments.

Though the absorption of hydrogen by iron is no doubt the cause of the frothing and diminution of toughness attendant on the immersion of iron in hydrochloric and sulphuric acids, there are some phenomena which

\* Proc. Lit. and Phil. Soc. Manch. 1874, p. 130.

ned by it alone, but which seem to show that the occlusion is accompanied by the absorption of a minute portion of pores of the iron.

his the following well-established facts are adduced :—

uch sooner regains its natural state after immersion in an in sulphuric acid, though at first both may have equally judged by diminution of toughness. It may be thought ion of the less volatile sulphuric acid adhering to the surface, even after prolonged washing, will account for it. This case however ; for the wire may not only be repeatedly er, but even coated with lime-water, dried, and finally re-ter two thirds by drawing several times through a steel which must surely remove any surface-coating of acid ; and e longer to recover its original toughness if cleaned in than in hydrochloric acid.

eces in the last experiment immersed in hydrochloric acid otted with rust on the surface some days before those im- phuric acid.

osition that acid is absorbed by the iron be correct, this is should expect ; for it is only natural to suppose that the most viz. hydrochloric, will come to the surface first.

moreover, that water can by great pressure be forced ldrable thicknesses of cast iron. Why, then, should not a

large numbers of iron articles are now coated with a covering of copper four thousandths of an inch in thickness.

In connexion with this subject, I wish to refute a statement made by Professor Reynolds, in a paper read before the Lit. and Phil. Society of Manchester, Feb. 24th, 1874, an abstract of which appeared in the 'Journal of the Chemical Society,' June 1874, p. 546, and other journals. The Professor states that I did not attribute the frothing of iron after immersion in acid to the escape of hydrogen, but to the action of acid. In my first paper on this subject (Proc. Lit. and Phil. Soc. Manchester, p. 80, 1873) the following passage occurs:—"It seems probable that a part of the hydrogen produced by the action of the acid on the iron may be absorbed by the iron, its nascent state facilitating this. And when the iron is heated, by the effort of breaking it, the gas may bubble up through the moisture on the fracture." This shows that in my first paper I comprehended the true nature of the phenomenon.

*Change produced in the breaking-strain and ultimate elongation of iron and steel by hydrogen occluded in it after immersion in hydrochloric and sulphuric acids.*

In the earlier part of this paper some few of the changes in the properties of iron produced by occluded hydrogen have been examined. The degree of this change it has not always been possible to determine. In the case of the diminution of toughness, for example, no exact and easily applied test has yet been devised by which we can obtain with precision a numerical result expressing the relative toughness of any two samples; consequently we must be content with less definite results. This difficulty is fortunately not met with in the examination of the change in elasticity and tensile strength; for the breaking-weight and maximum elongation of any number of samples can be pretty easily ascertained, with great accuracy, and numerically expressed, thus making comparison easy.

Bearing in mind the numerous uses of iron and steel, and the probability that at times hydrogen may be occluded in them, altering their strength in a way little anticipated, it seemed of some importance to determine these changes—and the more so, as any experiments of this kind could not fail to throw some light on the molecular arrangement of the metal in different qualities of iron and steel, a subject in itself of much interest. With this object upwards of 350 experiments have been made at various times with a very accurate machine, by which any weight could be brought to bear on the wire to be tested without the least jar—a very important point, though difficult of attainment, in experiments on tensile strength. The elongation at any moment could also be easily read off. The length of the pieces tested was in all cases the same, viz. 10 inches between the dies, and the temperature at the time of experiment about 16° C. I mention these points, as any variation in the length or tempe-

pieces tested will alter the result considerably. In order as far as possible, errors arising from the irregularity and non-homogeneousness of structure, even in the most carbon and steel, the number of tests has been multiplied as much as possible, and the mean only given.]

The experiment was as follows:—After immersion in acid, the pieces were washed and then tested, this giving the tensile strain and breaking-strain containing occluded hydrogen; subsequently they were heated in plates or in ovens, as the most ready method of expelling the gas, to a temperature considerably below that required to destroy the metal, and when cold, the breaking-strain &c. of the iron, after it had recovered its natural state, was again ascertained by testing.

It was thought that tests of iron in its natural state could be best represented by testing on it before immersion in acid. Results so obtained, however, be fairly compared with tests of the same piece after immersion in acid, as the action of the acid somewhat reduces the strength of the iron.

The results are the means of 30 tests made on *annealed* and *rolled* iron, respectively—first, after being one hour in hydrochloric acid, and secondly, after being heated 12 to 48 hours to drive off the gas.

ing-strain of the same, after being 5 days on a hot plate to expel the hydrogen, is as follows :—

	Break- ing- strain.	Mean error in breaking- strain.	Elongation of length tested.	Mean error in elongation.	Number of experiments for each result given.
		per cent.	per cent.	per cent.	
Charcoal-iron wire con- taining H occluded in $H^2SO^4$ .....	100	$\pm 1.33$	1.3	$\pm 0.23$	6
Charcoal-iron wire, H expelled by heat .....	106.62	$\pm 7.10$	4	$\pm 0.33$	6
Charcoal-iron wire con- taining H occluded in $HCl$ .....	100	$\pm 0.3$	1.41	$\pm 0.41$	6
Charcoal-iron wire, H expelled by heat .....	105.35	$\pm 1.1$	4.6	$\pm 0.33$	6

The diminution of elongation and breaking-strain caused by occlusion of hydrogen is very marked in these experiments, but is quite equalled by the following experiments on mild steel containing about 0.227 per cent. carbon. The wires were allowed to remain in very dilute hydrochloric acid about 5 hours, then, when tested, heated to about  $100^\circ C.$  for 12 hours, by which means a portion of the occluded H was expelled.

	Break- ing- strain.	Mean error in breaking- strain.	Elongation.	Mean error in elongation.	Number of experiments for each result given.
		per cent.	per cent.	per cent.	
Annealed mild steel containing H .....	100	$\pm 5.08$	20.1	$\pm 0.61$	9
Annealed mild steel, H partially expelled by heat .....	104.77	$\pm 3.81$	15.4	$\pm 1.2$	9
Bright mild steel be- fore immersion in $HCl$ .....	104.03	$\pm 10.1$	1.06	$\pm 0.44$	6
Bright mild steel con- taining H.....	100	$\pm 9.2$	2.8	$\pm 0.46$	6
Bright mild steel H partially expelled by heating 12 hours.....	108.68	$\pm 1.5$	2.16	$\pm 0.38$	6
Bright mild steel, H completely expelled by heating 7 days ...	114.29	$\pm 8.4$	3.42	$\pm 0.75$	6

These experiments show:—

1st. That the tensile strain of steel is diminished by the occlusion of hydrogen, and that as the hydrogen is expelled (a process of long duration)

risks, till eventually it exceeds the original strain before

expected change in the elasticity of steel, the elasticity is considerably increased by the occlusion of hydrogen; when of this hydrogen is expelled by heat, the elasticity, as measured at the moment of fracture, falls remarkably, as 10 per cent. in annealed and 0.64 per cent. in bright steel. When is completely expelled, the elasticity, however, rises, more than before immersion in acid.

Experiments on hardened and tempered cast-steel wire containing three times as much carbon as the mild steel, show an increase in the tensile strain when containing occluded hydrogen. However, is regained or even surpassed when the hydrogen is expelled by heat.

Break- ing- strain.	Mean error in breaking- strain.	Elongation.	Mean error in elongation.	Number of experiments for each result given.
	per cent.	per cent.	per cent.	
123.79	$\pm 2.7$	2.16	$\pm 0.27$	6
100	$\pm 4.9$	1.916	$\pm 0.416$	6

Professor Stewart kindly allowed me the use of the Owens College apparatus, with which some of the following results were obtained:—

Resistance of 6 feet bright charcoal-iron wire=100 .....	100
Resistance of 6 feet bright charcoal-iron wire after 5 hours in dilute $\text{H}^2\text{SO}^4$ = 107.14, or, allowing for iron eaten away by acid.....	105.6
Resistance of 6 feet bright charcoal-iron wire after 5 hours in dilute $\text{HCl}$ = 114.3, or, allowing for iron eaten away by acid .....	109.4

The wires were somewhat eaten away by the acid, so allowance had to be made for the increased resistance due to decreased sectional area; this is made in the column to the right.

About 50 feet of hard bright iron wire, after 24 hours' immersion in dilute sulphuric acid, gave a resistance of 2.94 ohms, and 2.92 ohms after the occluded hydrogen had been expelled by heat.

The above results, though far from uniform, are sufficient to show that there is an increase in the resistance of iron wire when it contains occluded hydrogen. I hope soon to make further experiments on this subject. It is worthy of remark that Professor Graham found the resistance of palladium containing occluded hydrogen was increased about 25 per cent. He also discovered that a palladium wire first elongated when charged with hydrogen, and then contracted when the hydrogen was withdrawn to less than its original length. The writer has detected a very small and similar change in the length of annealed iron wire under like condition, but has not yet observed it in bright iron wire, though he does not despair of doing so.

### *Diffusion of Hydrogen.*

A number of experiments were made by allowing one half of a piece of bright iron or steel wire to be acted on by dilute acid, and thus to occlude hydrogen while the other half was protected from this action, with a view of ascertaining if the occluded hydrogen could spread along the interior of the iron. Great difference was observed in the behaviour of iron and steel; the fibrous structure of iron wire allows the hydrogen occluded in the part acted on by acid to spread into the other part, distinct traces of hydrogen being observed 17 centims. from the part affected by acid. The close unfibrous structure of steel, on the contrary, seems to oppose this altogether, it being questionable if the hydrogen spreads 2 to 3 centims. beyond the part immersed in acid.

When that part of the iron wire which was protected from but still affected by the acid was broken and the fracture moistened, the bubbles of gas arose almost exclusively from the centre of the fracture, while from the part immersed in acid they arose equally from the whole surface, and took less time to attain their maximum.

Papers were read :—

Origin and Mechanism of Production of the Prismatic (Columnar) Structure of Basalt." By ROBERT F.R.S. Received December 12, 1874.

(Abstract.)

Having briefly traced the history of geological opinion on the subject before the period at which the controversy at which the aqueous origin of basalt might be viewed as settled, and the views of some of the more prominent British authors of recent date, points out that, up to the present, no clear prismatic views have been enunciated to account for prismatic structure, and that it is impossible to gather, with any distinctness from writers, whether prismatic structure be due to con-

indefinitely greater than that, and assuming the material at one temperature initially, homogeneous and isotropic, and that cooling takes place from the top surface only, he, on these data, proceeds to consider the phenomena that will successively result by contraction in cooling.

While the mass remains at its upper part still plastic by heat, contraction will be met by internal movements and subsidence of the top surface, and no cracking or splitting can take place until the material there has become rigid enough to break under tensile strain. He points out that this degree of rigidity, or "splitting temperature," is not reached until the top surface has fallen to between  $900^{\circ}$  and  $600^{\circ}$  Fahr.

At this temperature the cooling surface begins to separate, by fracture penetrating perpendicularly to it, into smaller surfaces. These must be similar and equal in area, and such as that their edges in contact can make up a continuous superficies. To relieve the orthogonal strains in the cooling surface, and to meet the above conditions, only three geometric figures for the separating surfaces are possible—namely, the equilateral triangle, the square, and the regular hexagon.

The author then inquires why the last of these is normally the form found in nature. He traces this to the law of least action which governs the play of all natural forces whose final result is produced by the least possible expenditure of force. He shows that, in a contracting surface splitting up into equal areas, the expenditure of work will, for the equilateral triangle, the square, and the regular hexagon, be approximately as the numbers 1.000, 0.680, and 0.519. This economy of force decides the hexagon as the form found in nature. The diameter of the hexagon, which is the upper surface of the inceptive hexagonal prism, is shown to be fixed by the relation that subsists between the coefficient of contraction of the material and that of its extension at rupture by a tensile force at the splitting temperature. This decides the diameters of the separate prisms. The splitting by contraction proceeds into the mass always in a direction perpendicular to the cooling surface; and at any instant the splitting is limited in its progress by the isothermal *couche* which is at the splitting temperature within the mass; for within that *couche* the mass is still plastic. In the case assumed, the prisms formed are straight and vertical. When the splitting has proceeded to some distance within the mass, the further cooling of each prism takes place, not only from the top, but from the sides; and the more important conditions influencing the latter in nature are pointed out.

Any one prism is coldest at its extremity, and its temperature increases along its length to the other end, where the splitting is still proceeding. The prism is hotter also, for any transverse section, as we approach its axis than about the exterior; differential strains in the longitudinal direction thus take place, by cooling and contraction, between the successive imaginary *couches*, taken from the exterior to the axis of the prism,

use the outer portions of the prisms to tear asunder at length dependent, like the diameter of the prisms themselves, on the subsisting between the coefficient of contraction and of rupture of the material.

contracts not only in its length, but in its diameter; transverse fracture of its surface, when it occurs, is therefore due to the action of two orthogonal forces, the one parallel to the axis of the prism referred to, and the other in a plane transverse to the axis. If these two forces are proportionate, the first to the length of the prism preceding joint or from its extremity, the second approximately to the semidiameter of the hexagon or mean radius of the prism, the resultant of these two, at any point taken round the prism, is directed to the axis and tending towards it in direction. As the fracture of a homogeneous solid always takes place transverse to the line of action of the force, the fracture producing a transverse joint takes place at the ends of the prism—the obliquity becoming less as the distance increases towards the axis of the prism, so that when compared with a cup-shaped fracture, the convex surface of the fracture always points in the same direction as that in which the splitting of the prism takes place.

The theory which is believed to be the first ever presented which, by the application of the laws, completely accounts for the production of the cup-shaped joints, is verified and illustrated by several

normal hexagonal form is returned to in such a manner as to require only the minimum expenditure of work.

The conditions producing greater or less interspaces between the prisms, which may vary from point to point of the same mass, are pointed out, as also those which cause the spaces between successive joints in adjacent prisms to coincide in successive planes, transverse to their axes or the contrary.

The author then proceeds to discuss the various positions in space, and relatively to each other, which the axes of the prisms must assume, dependent on the general law, as already stated, that the axes of the prisms, however produced, are always normal to successive isothermal *couches* or planes at the splitting temperature, taken in succession within the mass.

If the mass be tabular, as already assumed, and cooling take place only from the top surface, the prisms will be straight and vertical, extending from top to bottom nearly of the tabular mass, and being separated from the bottom on which it rests by a more or less thick layer of irregular angular fragments, or of badly conducting material, tufa, scoriæ, &c., the convex surfaces of the cross joints all pointing downwards. If the mass cool both from the bottom and the top, the prisms, vertical and straight, will split upwards and downwards, and meet in an irregular intermediate stratum of angular fragments, the convex surfaces of the joints of the lower prisms pointing upwards, and the respective lengths of the upper and lower ranges depending on their relative rates of cooling. If the tabular mass cool also from one or more of its sides, as by an abutting wall of rock, prisms will be produced with their axes perpendicular to that wall, and will be separated from the vertical ranges of prisms by an inclined stratum of angular fragments. Also, if the basalt fill a crevasse producing a dyke, the prisms formed by cooling will be generally transverse to the plane of its walls, and meet somewhere towards the centre in a stratum of more or less irregular fragments, due in all cases to the irregular contractions at the extremities of the prisms breaking up their mass there into wholly irregular forms. If the upper and cooling surface have a curved convex contour, the prisms will be taper and convergent from the surface of the mass; and, on the contrary, if the cooling surface have a concave contour, or rest upon a concave bottom, the prisms will be divergent from the interior of the mass, the natural law of economy of work limiting the length or amount of taper in either case and the length of the prisms, and at a certain length of prism a new range of larger diameter partially or wholly then commencing. The convergence or divergence are simple consequences of the general law, that the splitting takes place always normal to the isothermal *couches* which are at the splitting temperature.

The author then proceeds to develop and illustrate by diagrams some of the varied and curious combinations which are observable in nature,

more or less combined play of these conditions. He then develop, as a consequence of the general law, the production of, or those with apparently bent axes, which are observed in volcanic countries. If the cooling mass of basalt be in one position of such a form that successive isothermal *couches*, in the same order, are not parallel to the original cooling surface, but in all cases of straight and parallel prisms, but divergent from the cooling surface and from each other, then the lines of jointing of prisms, always normal to these *couches*, must be curved in the same manner. This will be true whether the isothermal *couches* be plane or curved, or whether the mass passes from a thinner to a thicker part of the mass, or whether the mass is deposited on surfaces arising from the mass reposing on a curved surface, or whether the mass is deposited in like manner. This explanation of the production of curved prisms, without the necessary intervention of external causes, is the author's having bent into curves prisms originally formed straight. The author believes, here for the first time presented. He has shown that no difficulties exist to the supposition that curved prisms result of the bending of prisms originally straight by mechanical effort. The author having thus shown that all the phenomena presented in nature by the forms, jointings, positions of columnar basalt are accounted for as consequences of cooling, submits that this solution given by him must be correct. He, however, proceeds to examine at some length the

distinct. The paper is chiefly a record of observations made by this method. The author shows :—

1. After a horizontal section of the cornea has been sealed up for about 24 hours, the stellate branched cells are seen to consist of a mass of protoplasm, sharply defined on every side, except where it is continued for a scarcely perceptible distance into the processes. The nucleus is flattened. The processes become very fine, glistening, and thread-like almost immediately after leaving the cell, and, by dividing and anastomosing with the processes of other cells, form a rich and very delicate network.

2. It sometimes happens, although only in rare instances, that, in gold preparations, fine dark lines extend between the nuclei, and correspond in outline and course with the processes seen in the aqueous humour; and it is then evident that they are surrounded by the dark-coloured tracts which form the ordinary network seen in gold preparations, and which correspond, in outline and varying degree of development in different animals, ages, and pathological conditions, with the corneal spaces.

3. Similar appearances to those described in paragraph 1 are seen in sections of cornea which have been 5 to 10 days sealed up in a 10-per-cent. solution of common salt.

4. The quadrangular and long narrow flat cells shown by the author to exist in the cornea, by means of a saturated solution of potash, are also rendered visible by the above method. They are best seen in oblique sections, from which, after 2 to 5 days, they fall out singly and in rows. A row of the long narrow cells is often seen to terminate in quadrangular cells at either end. These cells have a perfectly hyaline appearance; their nucleus has a very faint yellowish tinge, and projects beyond the surface of the cell.

In exceptional instances, in the uncut cornea of the frog, the long flat cells may be seen, after several days' maceration, lying on the primary bundles.

5. In tendon, flat masses of cells are found, on the third to fifth day, lying on the edge of the preparation and free in the fluid. The cells are accurately fitted to each other, after the manner of an epithelium. In the tendo Achillis of the frog they are seen of three sizes :—(a) large cells, corresponding to the flat cells seen on the surface by nitrate of silver; (b) smaller quadrangular cells, similar in size to those described by Ranvier, and which have been described by the author as investing the secondary and tertiary bundles in double layers; and (c) long, narrow, flat cells, similar to those described by the author as being isolable by potash, and as covering the primary bundles.

The masses of the cells of the surface, and of the secondary and tertiary bundles, can be usually seen to consist of a double layer separated by a very thin transparent medium.

6. The perimysium and neurilemma are respectively represented by a

of quadrangular and hexagonal cells, identical in general with an epithelium. Between the two layers there is a thin medium.

The neurilemma of the sciatic nerve of the frog, when cut in longitudinal strips, after a few hours, branched cells of different forms are seen isolated in the fluid near the cut edges. These are of two well-marked general types. In one a small smooth-surfaced mass of protoplasm is continuous at both ends with thread-like fibre; in another an irregularly contoured, but somewhat elongated, mass gives off numerous sharply defined, branching fibres in all directions. Sometimes a protoplasmic mass is attached at one end by a single fibre, and by two at the other. These are often of great length, and the protoplasmic mass can usually be found by carefully tracing them whilst moving the

The connective tissue is seen to be composed of uniform flat, ribbon-like structures whose breadth approaches the diameter of a human red blood corpuscle. These are seen in their simplest form when extruded from the sheath of the sciatic nerve of the frog, which takes place within a few minutes of dissection. From their position in this membrane they form a transparent medium which exists between the two layers of cells. They are mostly marked by a puckered appearance

vidual element bend in one direction until they join, and the substance of the ring thus formed undergoes in both a similar and peculiar process of disintegration. From these facts the author infers that the rods and cones of the retina are composed of fibrillary tissue in its simplest form.

12. Transverse sections of muscular fibre, when examined at intervals, show varying appearances, only a small minority of such preparations being successful. Successful preparations show one or more of three appearances :—(a) primary bundles, corresponding to Cohnheim's fields ; (b) groups of these (secondary bundles), the aggregate of which fill up the space bounded by the sarcolemma ; (c) a threadwork of fine fibres surrounding the primary bundles, in meshes.

13. Examination of connective tissue, in various stages of inflammation, yields strongly confirmatory evidence in favour of the interpretation given by the author to the appearances above described.

JOSEPH DALTON HOOKER, C.B., President, in the Chair.

The Presents received were laid on the table, and thanks ordered for them.

The following Papers were read :—

- I. "On the Theory of Ventilation : an attempt to establish a positive basis for the calculation of the amount of Fresh Air required for an Inhabited Air-space." By Surgeon-Major F. DE CHAUMONT, M.D., Assistant Professor of Hygiene, Army Medical School. Communicated by Prof. PARKES, M.D., F.R.S. Received November 18, 1874.

The question of ventilation, and the amount of fresh air required to keep an inhabited air-space in a sweet and healthy condition, has been much discussed of late years, and very fully treated of by various writers ; but there was a good deal of vagueness and want of precision in the manner of treatment previous to the Report of the Committee on Metropolitan Workhouse Infirmarys in 1867. In a paper in the 'Lancet' in 1866 I attempted to show that a more scientific method might be employed, and suggested some formulæ, which were quoted by Dr. Parkes in a paper appended to the Report above mentioned. Professor Donkin also investigated the question there, and in a short but exhaustive paper showed

Surgeon-Major F. de Chaumont on the [Jan. 28,

ffusion in an air-space being admitted, the same amount required to ventilate it, whatever its size might be. In published in the 'Edinburgh Medical Journal' in May into the subject with the view of pointing out that we might, data, establish a basis, which should be both scientific and estimating the amount of air required; and I adduced some that the evidence of the senses might be employed (if used re and precautions) as the ground-work of a scale, and gave of the amounts of respiratory impurity (estimated as  $\text{CO}_2$ ) ended to certain conditions noted as affecting the sense of paper attracted the attention of General Morin, who made short article in the Journal of the Conservatoire des Arts ing last year. Since the publication of my paper in 1867 ated more data; and the number of observations being now e at least a fair approximation to the truth, I beg to call e results.

ly admitted that it is organic matter, either suspended or vapour, that is the poison in air rendered impure by the spiration. It is also admitted that it is the same substance disagreeable sensation described as "closeness" in an ill-space. Although the nature of the organic matter may extent, it will be allowed that a condition of good ven-

struction, to enter the cells directly from the open air. All the results, therefore, have been obtained in buildings where this could be done, viz. barracks and hospitals, and the following are those examined :—

Aldershot Permanent Barracks.

Hilsea Barrack Huts.

Hilsea Hospital (Pavilion building).

Herbert Hospital (Pavilion), Woolwich.

Chelsea New Barracks.

Tower of London.

Gosport New Barracks.

Anglesea Barracks, Portsea.

Fort Elson

Fort Brockhurst } casemates.

Garrison Hospital, Portsmouth.

Civil Infirmary, Landport.

The plan followed in all was to take the observations chiefly at night, when the rooms or wards were occupied, and when fires and lights (except the lamp or candle used for the observation) were out. In this way all disturbing sources of  $\text{CO}_2$  were avoided, except in the occasional rare instances of a man smoking in bed or the like. On first entering the room from the outer air the sensation was noted and recorded just as it occurred to the observer, such terms as “fresh,” “fair,” “not close,” “close,” “very close,” “extremely close,” &c. being employed\*. Most of these notes were made by myself; but a good many were also made by my assistants, Sergeant (now Lieutenant) Sylvester in the earlier, and Sergeant H. Turner in the latter experiments. The air was then collected (generally in two jars or bottles, for controlling experiments), and set aside with lime-water for subsequent analysis, and the temperatures of the wet- and dry-bulb thermometers noted. About the same time samples of the external air were also taken, and the thermometers read. In this way any unintentional bias in the record of sensations was avoided, and this source of fallacy fairly well eliminated.

In some of the earlier observations the  $\text{CO}_2$  in the external air was not observed as constantly in connexion with the internal observations, partly because the importance of this was not so clearly perceived then, and partly from want of apparatus, the jars used being very bulky and not easy of carriage. It might therefore be argued that the *combination-weights* of the earlier experiments should be less in calculating the averages. I do not think, however, that this would amount to any sensible difference in the result, as the external  $\text{CO}_2$  ratios adopted from single experiments accord fairly with the mean ratio of the outer air†. In each

\* N.B. The terms used in the Tables are *exactly* those noted down at the time of observation.

† Mean ratio of the whole series .372; omitting those at Portsmouth Garrison Hospital, which were exceptionally low, .413.

Surgeon-Major F. de Chaumont *on the* [Jan. 28,

has been corrected for *temperature*, but not for *barometric* ; in some cases the reading of the barometer was not taken ; however, would not exceed on an average 1 per cent. The humidities were calculated from Glaisher's Tables.

The records of sensation are various in terms, I have thought it might be advantageously reduced to *five* orders or classes, as

including such expressions as "fresh," "fair," "not close," "pleasant smell," &c., indicating a condition giving no appreciable different sensation from the outer air.

including such expressions as "rather close," "a little close," "very foul," "a little smell," &c., indicating the point at which organic matter begins to be appreciated by the sense of

"close," indicating the point at which organic matter begins to be decidedly disagreeable to the sense of smell.

"very close," "bad," &c., indicating the point at which organic matter begins to be offensive and oppressive to the senses.

"extremely close," "very bad," &c., indicating the point at which the maximum point of differentiation by the senses is reached.

thus obtained shown as another means of estimating the value of the series.

*Analyses of the different Orders.*

No. 1 (see Table No. 1)\*.—“ Fresh ” &c. : a condition of atmosphere not *sensibly* different from the external air.

1. *Temperature*.—The experiments were made during both winter and summer, so that there is a good deal of variation in the external temperature, and the mean is some degrees above the mean annual temperature of this country (southern part of it), viz.  $57^{\circ}47$ . The mean in the inhabited air-spaces is  $62^{\circ}85$ , or  $5^{\circ}38$  higher. This is a moderate difference, and shows a good average temperature for dwelling-rooms. The maximum range is  $10^{\circ}$  ( $57^{\circ}89$  to  $67^{\circ}81$ ), calculated from the error of mean square, the actual extremes being  $77^{\circ}$  and  $53^{\circ}$ .

2. *Vapour and Humidity*.—As the external temperature varied considerably, so also did the amount of vapour, the mean being 4.285, equal to about 80 per cent. of humidity. The internal observations showed a mean of 4.629, or 73 per cent. of humidity, being an excess of vapour of 0.344 of a grain, and a lowering of relative humidity equal to 7 per cent.

3. *Carbonic Acid*.—The mean external carbonic acid was 0.4168, a little above the usual amount. The mean in the inhabited air-spaces was 0.5998, or an excess of 0.1830, the mean error being 0.0910. The probable error of a single observation is 0.0831, so that the truth would lie between 0.2661 and 0.0999; whilst the probable error of the result is only 0.0078, the range being between 0.1908 and 0.1752; we are therefore entitled to say that the limit of impurity, imperceptible to the sense of smell, lies at or within 0.2000 volume of  $\text{CO}_2$  per 1000 as a mean. From these data, then, we may lay down as conditions of *good* ventilation the following :—

Temperature about  $63^{\circ}$  Fahrenheit.

Vapour shall not exceed 4.7 grains per cubic foot.

Carbonic acid shall not exceed the amount in the outer air by more than 0.2000 per 1000 volumes.

No. 2 (see Table No. 2).—“ Rather close ” &c. : a condition of atmosphere in which the organic matter begins to be appreciated by the senses.

1. *Temperature*.—In this series the external temperature (although still above the mean temperature of this climate) was rather lower than in the previous one, viz.  $54^{\circ}85$ , whilst the internal observations gave a mean of  $62^{\circ}85$  (the same as in No. 1), or a difference of  $8^{\circ}$ .

2. *Vapour and Humidity*.—Although the temperature was the same as in No. 1, the amount of vapour in the inhabited air-spaces was greater,

\* It has not been thought necessary to publish Tables 1–5, but they are preserved in the Archives of the Society.

Surgeon-Major F. de Chaumont *on the* [Jan. 28,

and relatively, the excess being 0·687 of a grain and the humidity being about 7·6 per cent.

*Acid.*—The mean amount in the outer air was 0·4110 per cent, in the inhabited air-spaces 0·8004, or a mean difference (impurity) of 0·3894. The range for the probable error of mean was between 0·4057 and 0·3731.

I therefore say that ventilation ceases to be *good* when the following conditions are present :—

1. The air exceeds 4·7 grains per cubic foot.

2. The excess over outer air, ratio reaching 0·4000 per 1000 volumes.

3. (See Table No. 3).—"Close" &c.: the point at which the carbonic matter begins to be decidedly disagreeable to the senses.

*Temperature.*—The temperature in this series was more near the climate, viz. 51°·28. The mean in the inhabited air-space was 52°·91, a mean excess of 12°·91.

*and Humidity.*—The vapour in the outer air was 3·837, and in the inhabited air-space 4·909, a mean difference of 1·072 grain per cubic foot. The drying of the air amounted to a lowering of the humidity of 27·6 per cent.

*Acid.*—The carbonic acid in the outer air was 0·3705 per

0·8432, the range for probable error of result being between 0·8640 and 0·8224.

We may say that ventilation is *very bad* when :—

Vapour reaches 5 grains per cubic foot.

Carbonic acid in excess over outer air reaches 0·8000 per 1000 volumes.

No. 5 (see Table No. 5).—“Extremely close” &c. : the maximum point of differentiation by the senses.

1. *Temperature*.—The temperature in the outer air was 51°·86, and in the inhabited air-spaces 65°·05, giving a mean difference of 13°·19.

2. *Vapour and Humidity*.—The mean vapour in the outer air was 3·875, and in the inhabited air-spaces 5·194, showing an excess of 1·319 grain, corresponding to a lowering of relative humidity of 9·88 per cent.

3. *Carbonic Acid*.—The mean amount in the outer air was 0·4001, or exactly the average amount. In the inhabited air-spaces it was 1·2818, showing an excess due to respiratory impurity of 0·8817 per 1000 volumes, the range for the probable error of result being between 0·9202 and 0·8432.

The extreme point of differentiation by the senses is thus reached when the following conditions are found :—

Vapour 5·100 grains per cubic foot.

Carbonic acid in excess over the amount in the outer air beyond 0·8500 per 1000 volumes.

It will at once be seen that the figures in No. 5 differ but little from those in No. 4, and that the probable *limit of differentiation* by the senses is reached in No. 4. The number of recorded observations in No. 5 is also very few comparatively ; and I think it would therefore be better to group the two together, as below.

Nos. 4 and 5 combined, being the probable limit of possible differentiation by the senses.

1. *Temperature*.—In the outer air 51°·43, in the inhabited air-spaces 65°·12, or a mean difference of 13°·69.

2. *Vapour and Humidity*.—The vapour in the outer air was 3·729, inside 5·108, or a mean difference of 1·379 grain, corresponding to a lowering of relative humidity of 8·92 per cent.

3. *Carbonic Acid*.—In the outer air 0·3928, in the inhabited air-spaces 1·2461, or a mean difference due to respiratory impurity of 0·8533, the range for probable error of result being between 0·8717 and 0·8349.

We may therefore, I think, say that when the vapour\* reaches 5·100 grains per cubic foot, and the CO<sub>2</sub> in excess 0·8000 volume per 1000, the maximum point of differentiation by the senses is reached.

\* It is to be understood that the amounts of vapour stated in these cases are in reference to a mean temperature of about 63° F.

Surgeon-Major F. de Chanmont *on the* [Jan. 28,

to the Tables it will be seen that there is a regular  
pass from one order to another. The following  
is:—

Temperature.		Vapour.		Carbonic acid.	
	Excess over outer air.	In air- space.	Excess over outer air.	In air- space.	Excess over outer air.
5	5.38	4.629	0.344	0.5999	0.1830
6	8.00	4.823	0.687	0.8004	0.3824
7	12.91	4.909	1.072	1.0027	0.6322
8	13.87	5.078	1.400	1.2335	0.8432
9	13.19	5.194	1.319	1.2818	0.8817

is complete in the carbonic acid, although there are  
variations in the temperature and vapour of No. 5. Taking  
the mean, we have

2      13°.69      5.108      1.379      1.2461      0.8533

the next order. The average rates of progression (including the actual excess in No. 1) are :—

Temperature.	Vapour.	Carbonic acid.
3°·42	0·345	0·2133

Here the amount of vapour is exactly the actual excess in No. 1, and the amount of carbonic acid somewhat in excess; the mean, however, between this amount and the actual recorded excess in No. 1 is as follows :—

Actual excess over outer air in No. 1	.....	0·1830
Mean of progressive increase, as above	.....	0·2133
		<hr/>
Sum	.....2)	0·3963
		<hr/>
Mean	.....	0·1982

This is sufficiently close to 0·2000 to furnish some additional reason for adopting this latter number as the limit of respiratory impurity admissible in *good ventilation*.

*Values of the several series, considered relatively to each other.*

The values are important as a guide to the more or less trustworthy character of the series. They have been calculated out in three ways :—

- 1. As the reciprocal of the square of *mean error*.
- 2. As the reciprocal of the square of probable error of result.
- 3. As the ratio between the *modulus* calculated from the *mean error* and the *modulus* calculated from the *error of mean square of a single measure*.

The following Table gives the values from the first method, viz. as reciprocal of the square of mean error :—

No.	Temperature.	Vapour.	Humidity.	Carbonic acid.
1. ....	0·0821	6·1300	0·0190	122·0000
2. ....	0·0625	3·1300	0·0140	34·0000
3. ....	0·0403	2·6500	0·0110	21·8000
4. ....	0·0543	2·7700	0·0120	17·0000
5. ....	0·0664	1·3700	0·0090	14·1000
4 & 5 combined	0·0610	2·2900	0·0010	16·5000

and the ratios, taking No. 1 as 1000, are :—

1. ....	1000	1000	1000	1000
2. ....	760	510	735	277
3. ....	492	431	575	178
4. ....	662	450	630	139
5. ....	810	224	473	115
4 & 5 combined	745	374	526	135

Surgeon-Major F. de Chaumont *on the* [Jan. 28,

that there is a diminution of value pretty regular up to here is a rise in No. 4 and No. 5 in the temperature, a rise and fall in No. 5 in the vapour and humidity, whilst the fall is throughout in the carbonic acid.

the result of the combination of 4 and 5 gives a number its proper place after No. 3, except in the temperature.

ing Table gives the values according to the second method, and the square of the probable error of the result :—

Temperature.	Vapour.	Humidity.	Carbonic acid.
.. 5.2716	293.93000	1.2656	16378.2000
.. 4.1165	324.2300	0.5318	3750.4000
.. 3.7470	281.3300	1.0966	4148.1000
.. 3.7100	170.000	0.5439	2307.5000
.. 1.5839	34.2770	0.1986	674.3000
med. 5.3171	195.8300	0.7708	2957.5100

, taking No. 1 as 1000, are :—

.. 1000	1000	1000	1000
.. 781	1103*	420	229
.. 711	957	867	253
.. 704	578	432	141
.. 302	117	157	41
med. 1008*	667	609	181

Table showing the same from Probable Error of Result.

No. of Order.	Product.	Ratio.
1. ....	32139057	1000·00
2. ....	2661995	83·00
3. ....	4794655	149·00
4. ....	791570	25·00
5. ....	7254	0·23
4 & 5. ....	2373680	74·00

Here we see a greater irregularity, No. 3 showing a superiority over No. 2, due probably to the greater number of individual observations in the former case.

Taking the mean of the ratios by the two methods, we have:—

No.	No.
1 = 1000	4 = 144
2 = 439	5 = 49
3 = 184	4 & 5 = 135

But the discrepancy in the ratios of the values from the probable error, where No. 3 exceeds No. 2, is due to the irregularity in the humidity column; and as this is not an independent quantity, but dependent on the temperature and vapour, we may legitimately omit it. We shall then have the products as follows:—

Values from Mean Error.

No.	Value.	Ratio.
1. ....	61·40	1000
2. ....	6·65	108
3. ....	2·33	38
4. ....	2·56	41
5. ....	1·28	21
4 & 5. ....	2·30	38

Values from Probable Error of Result.

No.	Value.	Ratio.
1. ....	25382435	1000·00
2. ....	5005632	197·00
3. ....	4372692	172·00
4. ....	1455360	57·00
5. ....	36526	1·44
4 & 5. ....	3079500	121·00

It will be seen that in the calculation from mean error there is a rise at No. 4 in both instances, i. e. with and without the humidity. There is a fall at No. 5, whilst the combined series 4 and 5 gives a result which follows naturally after No. 3. We may now reject Nos. 4 and 5 as sepa-

consider them in combination, when we shall have the  
values :—

	From Mean Error.		From probable Error of Result.
.....	1000	.....	1000
.....	108	.....	197
.....	38	.....	172
.....	38	.....	121

of the two values will be :—

..... 1000	No. 3.....	108
..... 153	Nos. 4 & 5....	80

by a series of ratios which follow a regularly descending  
in the order we might have expected *à priori*, seeing  
of smell is naturally less acute as the organic matter  
amount. But it is of less consequence to determine the  
higher orders in the scale, except as a measure of the  
of the observations throughout the inquiry, the really  
being the very great superiority of the first order, parti-  
cularly the carbonic acid. This is an additional argument for  
the limit of admissible impurity in good ventilation.  
of fresh air necessary to keep the impurity down to the  
would be according to the following formula,

I think that the general opinion is that Angus Smith's results give too low an estimate, and that 0·600 is really the lowest that can be with safety admitted.

The existing Army Regulations contemplate a delivery of 1200 cubic feet per head per hour in barracks; but practical inquiry has shown that this amount is generally fallen short of. The result is that the life of the soldier, at least during his sleeping-hours, is passed in a No. 3 air-space, or one in which the organic impurity is *decidedly disagreeable to the senses*. Previous to 1858 he did not even get this moderate amount of air; so that his life was spent in an air-space in which the organic matter was *offensive and oppressive to the senses*. If we adopt (as proposed already) 0·2000 per 1000 of CO<sub>2</sub> as the limit of impurity, then 3000 cubic feet per head per hour is the amount which must be delivered, on the supposition that  $e=0\cdot600$ , or 3525 if  $e=0\cdot705$ .

We may say, in conclusion, that the experimental data already quoted fairly justify the adoption of the following conditions :—

*Conditions as the Standard of good Ventilation.*

*Temperature* (dry bulb) 63° to 65° Fahrenheit.

„ (wet bulb) 58° to 61° „

N.B. The temperature should never be very much below 60°, but it may be found difficult to prevent its rising in hot weather. In any case the difference between the two thermometers ought not to be less than 4°, and ought not to exceed 5°.

*Vapour* ought not to exceed 4·7 grains per cubic foot at a temperature of 63 F., or 5 grains at a temperature of 65° F.

*Humidity* (per cent.) ought not to exceed 73 to 75.

*Carbonic Acid*. Respiratory impurity ought not to exceed 0·0002 per foot, or 0·2000 per 1000 volumes.

Taking the mean external air ratio at 0·4000 per 1000, this would give a mean internal air ratio of 0·6000 per 1000 volumes.

By considering separately the conditions found in barracks and in hospitals, or among healthy and among sick men, a point of some interest and importance seems to be indicated—namely, that more air is required for the latter than for the former to keep the air-space pure to the senses. This is due either to the greater quantity of organic matter or to a difference in its quality and nature. The following results are found from the data in the Tables :—

	Barracks.	Hospitals.
Mean amount of carbonic acid per 1000 volumes as respiratory impurity found when the air was noted as “fresh” &c., the impurity not being appreciable to the senses . . . . .	0·196	0·157
Number of analyses in each group . . . . .	75	38

# *On the Theory of Ventilation.*

.....	3062	3822

ound numbers, therefore, we may say that while a barrack-  
kept sweet with 3000 cubic feet, it will take 4000 to  
al ward containing ordinary cases in the same condition.  
ould, of course, be required during times of epidemic or

s regularity in the higher orders ; but if the whole of the  
other than No. 1, are taken together, we find a similar

	Barracks.	Hospitals.
of carbonic acid per 1000 volumes, as		
impurity, in all the observations, when		
matter was appreciable by the senses..	0·601	0·580
analyses in each group.....	274	86

the amount of air supplied as above, we have :—

201.]

TABLE (*Summary*) showing the *Leaders*,  
with

Details given in the columns under c	Nos. 4 & 5 com- bined,
	Being the proba- ble limit of pos- sible differen- tiation by the senses.
ence between external and internal air	+0.8533
of series of observations .....	0.2465
mean error .....	+1.0998
	+0.6068
mean square of a single observation .....	0.2949
do. ....	+1.1482
	+0.5584
error of a single observation ..	1.1111
do. ....	+1.0432
	+0.6634
mean square of the result	0.2222

Adopting the above numbers as the respective numerical values of each order, we have for *barracks* :—

No. of order.	No. of observations.	Value of order.	Total.
2. . . . .	89 ×	2·13 =	189·57
3. . . . .	88 ×	3·46 =	304·48
4 & 5. . . . .	97 ×	4·66 =	452·02
Sums . . .		274	946·07

giving a mean of 3·45.

For *hospitals* we have :—

2. . . . .	20 ×	2·13 =	42·60
3. . . . .	46 ×	3·46 =	159·16
4 & 5. . . . .	20 ×	4·66 =	93·20
Sums . . .		86	294·96

giving a mean of 3·43.

Here we find the same numerical value (signifying *close*) applied to 0·580 in hospitals and 0·601 in barracks. There is thus, even in this comparatively limited number of observations, a confirmation of the opinion that more air is necessary to keep an air-space sweet in disease than in health. It is, however, right to point out that in the one case the occupation was continuous, and in the other chiefly at night only.

II. “On the Atmospheric Lines of the Solar Spectrum, illustrated by a Map drawn on the same Scale as that adopted by Kirchhoff.” By J. B. N. HENNESSEY, F.R.A.S. Communicated by Prof. STOKES, Sec.R.S. Received, the map June 9, 1874, the text January 11, 1875.

(Abstract.)

The spectroscopic observations described in this paper were made with instruments belonging to the Royal Society, and in accordance with certain suggestions which had been made to the author by a committee appointed in consequence of a letter of his to Sir Edward Sabine, President, dated 13th February, 1866. In view of his residence at a considerable height above the sea-level, and of the exceedingly clear atmosphere prevailing at some periods of the year, it was suggested that the locality was peculiarly favourable for a determination of the lines of the solar spectrum due to atmospheric absorption, and that, for this purpose, the solar spectrum when the sun was high should be compared with

*On the Lines of the Solar Spectrum.*

[Jan. 28,

t sunset, and any additional lines which might appear in should be noted with reference to Kirchhoff's map.

the author set to work with the spectroscope first supplied the autumns of 1868 and 1869 mapped the differences in the extreme red to D. These results appeared in the 'Transactions of the Royal Society' for June 16, 1870, and the map of the high and sun low, of the region in question forms plate 1 of the second volume.

The instrument first supplied to the author was found in practice to be of insufficient power to permit of ready identification of the lines of the spectrum of the sun when high with those represented in Kirchhoff's map; and a new spectroscope of greater power was supplied which reached him at the end of the year 1871. Observations in continuation of his map had, in the mean time, been taken with the new instrument in the autumns of 1870 and 1871, and the spectrum was mapped from D to F, in continuation of the former map. But the new instrument proved so superior to the old, that the author determined to re-map the whole spectrum afresh from observations made with the new instrument. The former maps merely as skeleton forms. The observations with the new instrument were carried on in the autumns of 1872 and 1873, and the map now presented is the result.

Observations were also made to ascertain whether any of the lines

G. Gulliver, F.R.S.

“On the alleged Expansion in Volume of various Substances in passing by Refrigeration from the state of Liquid Fusion to that of Solidification.” By ROBERT MALLETT, F.R.S. &c. Received April 28, 1874\*.

The fact that water expands in becoming ice, and that the latter thus floats upon the water, can scarcely have escaped the observation or inference of the acute intellects of a remote antiquity. Its conditions, when more carefully examined in modern times, pointed out the strange and, as it has been called, anomalous fact that water can be cooled  $7^{\circ}$  or  $8^{\circ}$  below its freezing-point without becoming solid, and that between its maximum density at about  $39^{\circ}$  Fahr. and its freezing-point at  $32^{\circ}$  Fahr., or within the narrow range of  $7^{\circ}$  Fahr., it expands in the large ratio of 915 : 1000.

Standing thus alone amongst observed phenomena in nature, it seems to have suggested to many experimenters the question whether other bodies when liquefied by heat might not also expand when becoming solid by refrigeration. I have not attempted to trace with minuteness the history of past inquiry upon this subject, many loose uncertain statements as to which have for at least a century continued to perplex scientific literature. Réaumur appears to have been the first who gave currency to the statement that cast iron, bismuth, and antimony all expand in consolidating. The like fact has been alleged or left to be inferred with respect to the following substances by the authorities named:—

Silver, Persoz.

Copper, Karsten.

Mercury and Gold, as inferred by Nasmyth and Carpenter.

\* Read June 11, 1874. See ‘Proceedings,’ vol. xxii. p. 386.

Mr. R. Mallet on the alleged Expansion

furnace-slugs, by experiment of Heunter and Snelus, as Nasmyth and Carpenter.

It is the only body, in addition to water, that really appears to contract in consolidating is bismuth; and even this the author accepts on the basis of his own experiments, but accepts the fact, generally, as true upon the uncontradicted statements of many others, and upon the positive assurance which he is permitted to give Mr. John Tyndall that he is satisfied of its truth. With the exception of others, it is the object of this communication to show that the evidence in support of the alleged fact of expansion by refrigeration is weak and insufficient, and to offer with respect to cast iron, and with respect to iron furnace-slugs, experimental proof of the contrary statement.

It is not stated but only collateral facts, having regard to so-called anomalies of volume due to temperature, will not be referred to as an example, as the anomalous expansion of Rose's fusible alloy expands progressively, like other bodies, till it attains the temperature of  $11^{\circ}$ ; it then contracts rapidly by added heat to  $150^{\circ}$ , when it contracts again (see Graham's 'Elements,' vol. i., and Gmelin's 'Handbook'), the contraction here probably due to the successive segregation in the alloy of metals differing from each other in constitution, dilatibility, &c. Or, again, the facts observed with respect to the ex-

accepted and become current from book to book of authors up to the present day, as when Dr. T. Thomson ('System of Chemistry,' vol. i. p. 375, 5th edit.) says of cast iron that "it contracts considerably when it comes into fusion," or that of Kerl ('Metallurgy of Iron,' Crookes and Röhrig's translation, vol. ii. p. 291), that cast "iron occupies a smaller space after cooling than when in the liquid state; it contracts in such a manner that, at the commencement of its solidification, it first expands so as to be able to fill up the smallest depressions and cavities of a mould, but after solidifying it contracts"—a loosely worded statement, which in various forms may be found in a great number of authors upon metallurgy and technology. So likewise the statement often repeated, that the value of antimony in type-metal consists in its causing the latter to expand upon consolidation and so perfectly fill the matrix, is presented, so far as the author's reading goes, without the slightest experimental proof of its truth, and appears to rest simply upon Réaumur's statement with respect to antimony itself, which, as already mentioned, has been controverted by Marx. This subject, however, has now assumed greater importance, since it has recently been made by Messrs. Nasmyth and Carpenter the foundation upon which they rest their theory of lunar volcanic action, as presented to us by the surface of our satellite; and the object of the present communication is to show that, as regards the two most pertinent of the substances adduced by these authors, viz. cast iron and iron furnace-slag, the facts entirely fail in support of their theory.

First, then, as to cast iron. It is not a fact that all cast iron in the solid state will float upon all cast iron in liquid fusion, though such might be inferred from the broad and loose statements of authors. Even in the limited form in which the statement is made by Nasmyth and Carpenter—viz. "that when a mass of solid cast iron is dropped into a pot of molten iron of identical quality the solid is found to float persistently upon the molten metal, so persistently that when it is intentionally thrust to the bottom of the pot it rises again the moment the submerging agency is withdrawn" ('The Moon,' p. 21)—is not quite exact.

It is a fact that certain pieces of cast iron in the solid and cold state will float on certain descriptions of cast iron in liquid fusion; but whether the solid pieces shall float or not float in any given case is dependent at least upon the following conditions, and probably upon others not yet ascertained:—

1st. Upon the relative specific gravities of the solid and of the fused cast iron both referred to the temperature of the atmosphere. Under the commercial name of cast iron is comprehended a wide range of compounds of iron with other substances, which compounds differ greatly in their physical as well as their chemical qualities, and have a range of specific gravity of from nearly 7·7700 for the whitest, most rigid, and dense, down to little more than 6·300 for those which are darkest, softest, and most porous. The total dilatation at the fusing-point of the denser

Mr. R. Mallet on the alleged *Expansion*.

own to be somewhat greater than that of the less dense ;  
se in volume may not be sufficient to equalize the spe-  
very dense iron when in fusion with that of a very light  
so it is obvious that a piece of cold cast iron might be  
ference to its specific gravity, as referred to that of  
cast iron in fusion, that the former should either sink or  
atter by mere buoyancy, were that free to act alone.

g the cold and the molten cast iron originally identical  
ther a piece of the former shall float or not float upon  
is not only upon buoyancy as above, but also upon the  
e of cold metal -that is to say, on the relation, all other  
same, that subsists between its volume and its surface.  
e, whatever be its nature, which keeps the piece of cold  
s of sufficient energy to overcome a considerable want of  
cold iron under certain conditions, so that it may float  
iron whose specific gravity, as such, is much less than  
er iron which floats upon it. Messrs. Naamyth and  
e, without any sufficient proof, that solid cast iron floats  
the same quality in virtue of buoyancy alone, and pro-  
" the inevitable inference from this is that in the case  
solid is specifically lighter than the molten, and there-  
ng from the molten to the solid condition, this substance  
not include " & The Motion of the

the walls of the vessel being about  $\frac{1}{2}$  in. in thickness.' It was perfectly smooth in the inside, and the plane of the lip of the open neck was carefully made parallel to the plane of the base. This vessel weighed, when empty, 184.75 lbs. avoirdupois. The orifice of the neck being levelled as the vessel stood upon the platform of the weighing-apparatus, it was filled up to the exact level of the neck with water at a temperature of  $60^{\circ}5$  Fahr., and again weighed. Deducting the weight of the empty vessel, the weight of its contents of water was found to be 94.15 lbs. avoirdupois. From the known volume and weight of the imperial gallon of distilled water, the capacity of the vessel was therefore at  $60^{\circ}$  Fahr. = 2605.5 cubic inches. As a check upon the results, both as to weight and capacity, the water was measured into the vessel from accurate glass standards of volume. The water employed was that from the well at Messrs. Maudslay, Sons, and Field's Engine Works, Lambeth, where these experiments were conducted, and to whose liberality the author owes the means of having performed them. The specific gravity of this well-water did not very materially exceed that of distilled water, being about 1.0004; but if we apply the necessary correction, the weight of the contents of the iron vessel of distilled water at  $60^{\circ}$  Fahr. is 94.112 lbs. avoirdupois. The vessel being emptied, carefully dried and warmed, and stood upon a hard rammed bed of dry sand with its neck perfectly level as before, was now filled perfectly level to the brim with molten cast iron. As the temperature of the vessel itself rapidly rose by contact with the large mass of molten iron within it, and by its dilatation had its capacity enlarged, so the top surface of the liquid cast iron within it rapidly sank, fresh additions of molten iron being constantly made to maintain its top surface level with the brim. This was continued until the whole of the exterior of the vessel was seen to have arrived at a clear yellow heat, beyond which no increase to its temperature took place. At about twenty minutes after the molten iron was first poured into the vessel, this point was reached, the feeding in of additional iron being discontinued a few minutes previously. The whole being left to cool for three days, the vessel full of the now cold and solid cast iron was again weighed; on deducting, as before, the weight of the empty vessel, the weight of the cast iron which filled it was found to be 645.75 lbs., which, with certain corrections to be yet noticed, was the weight of cast iron which, when in the molten state, was equal to the capacity of the conical iron vessel in its expanded state due to its exalted temperature. We have now to determine what was the capacity of the vessel in this expanded state. The temperature at which cast iron melts may be admitted as about  $2400^{\circ}$  Fahr.; but as iron tapped from the cupola is always above its melting-point, we may admit that it was poured into the vessel at  $2600^{\circ}$  or  $2700^{\circ}$  Fahr., the surplus heat in the cast iron, whose mass was about four times that of the wrought-iron vessel which contained it, being given off in the first instance to heat the latter. The temperature at which

### Mr. R. Mallet on the alleged Expansion

presents to the eye a clear yellow visible in daylight may, with the views of most physicists, be taken as between the of silver and of gold, or at  $2000^{\circ}$  Fahr. The mean coefficient of dilatation for  $1^{\circ}$  Fahr. of wrought iron has been determined by Laplace, Smeaton, Troughton, and others, the limits of zero and  $212^{\circ}$  by Laplace, Smeaton, Troughton, and the average of the four being 0.00000699 for  $1^{\circ}$  Fahr.; and by below the truth for the whole range of temperature up to the rate of expansion of all fusible bodies appears to increase with temperature. Rinmann has determined the linear dilatation of a bar of iron, when raised from  $60^{\circ}$  Fahr. to a white or welding heat, of its length, or .0125; and taking the total range of temperature at  $2400^{\circ}$ , we have a mean coefficient of linear dilatation for  $1^{\circ}$  Fahr. This is a still smaller coefficient than the present author has, however, preferred to adopt it in order to avoid exaggerate in his own favour the results arrived at. Applying Rinmann's coefficient to the dimensions of the cone at  $60^{\circ}$  Fahr. its temperature ( $2000^{\circ}$  Fahr.) when at the maximum, we deduce the true capacity of the cone when expanded to the temperature of molten iron, viz. = 2691.77 cubic inches. The vessel was now cut off by a circular cut at the base and down the side of the cone, and separated from the conical part. When it had filled it, the interior surface of the iron vessel was

taken by the usual methods, proved to be 7.170, which may be taken as the mean specific gravity at 57° Fahr. of the whole of the cast iron that filled the cone. Reverting now to the conical vessel which contained at 60° Fahr. 94.112 lbs. of distilled water, its capacity being 2605.5 cubic inches: this capacity was enlarged by expansion when filled with molten iron to 2691.777 cubic inches, so that the conical vessel when cold, if it had had the same capacity as when filled with liquid iron, would have contained 97.224 lbs. of distilled water. We have now all the elements necessary for calculating the specific gravity of the cast iron which filled the cone in its molten state, because we have the actual weights of equal volumes of distilled water and of molten iron. The final results, then, are, that whereas the cast iron which filled the cone had when cold (57° Fahr.) a specific gravity, as above given, = 7.170, the same cast iron in its molten state, as poured into the cone, had a specific gravity of only 6.650—in this case thus proving that the density of cast iron in its liquid state is not greater but, on the contrary, very much less than that of the same cast iron at the temperature of the atmosphere. The quality of cast iron employed in this experiment was the fine, bright, close-grained metal usually employed by Messrs. Maudslay, Sons, and Field for their engine-castings, and consisted of

$\frac{1}{4}$  Gartsherrie, } Scotch,  
 $\frac{1}{4}$  Coltness, }  
 $\frac{1}{2}$  Best scrap\*—all by weight.

It may be taken as a typical or medium example of all good grey cast irons. I have not been enabled to repeat this experiment with the white, rigid, and crystalline cast irons, such as are employed for projectiles and other purposes; but as it is a recognized fact amongst iron-founders that these irons expand in the range of temperature between solidity and liquidity *much more* than do grey irons, so we may justifiably conclude that the decrease of specific gravity by fusion of these hard cast irons would be in even a greater ratio than that shown by the above experiment on grey iron; and generally the author feels himself justified in concluding that it is not true that *any* cast iron is denser in the fused than in the solid state. Cold cast iron, therefore, does not float upon liquid cast iron of the same quality by reason of its buoyancy, but in virtue of some force which tends to keep it upon the surface of the molten metal in opposition to a very considerable want of buoyancy or tendency to sink by greater density on the part of the solid iron, which is, by the preceding results,  $\frac{1}{13.8}$  of its weight, whatever that may be, and is probably even greater than this in the case of hard white cast irons. The author's chief object has been thus far rather to prove that the cause assigned by the writers already mentioned is *not* the true cause of the floating of solid upon liquid cast iron of the same quality. What is the nature of the force which pro-

\* Disused and broken-up castings.

### Mr. R. Mallet on the alleged Expansion

ous phenomenon and often in direct opposition to gravity, and a much more delicate and difficult inquiry, which he has left to the physicists to fully investigate. The following experiments, which have been placed on record as tending to afford some little dawn on the subject.

Some experiments were made with pieces of iron cast from the same quality as that which filled the experimental cone, and immersed in molten cast iron of like quality with themselves such can be secured by "tapping" at nearly the same time from the same cupola charged with the same materials.

In order to describe these, it will be necessary to deduce from the experiments a mean coefficient of total cubic dilatation for the range between  $60^{\circ}$  and  $2400^{\circ}$  Fahr. for the grey cast iron employed in the experiments. The total dilatation was, as we have seen, equal to the specific gravity of the cast iron when cold ( $=7.17$ ) to its weight when fused. The cubic dilatation was therefore in the inverse ratio of the numbers, or as  $1000 : 1078$ ; and dividing this increase in  $2400^{\circ}$  Fahr., the total range of temperature, we obtain for the coefficient of cubic dilatation of this grey cast iron for  $1^{\circ}$  Fahr. or approximately for its mean coefficient of linear dilatation  $0.000111$ . These coefficients are nearly double those obtained by Lavoisier for a range of temperature of  $180^{\circ}$  Fahr., and  $0.000212$ , which is quite what we should expect, as the

These preliminary explanations will enable us better to interpret the following experiments.

*Experiment 1.* An irregular piece, believed to be of hard and dense cast iron, and also a ball of about  $2\frac{1}{2}$  in. diameter, believed to be of close-grained grey iron: both sunk to the bottom when thrown into the ladle of liquid iron, and remained for some time at the bottom; both, however, reappeared upon the surface when they had acquired a temperature sufficient to have fused off portions of their respective masses.

[In every fresh-lined ladle of liquid cast iron there are circumferential ascending and central descending currents in the metal, produced by the gases evolved from the lining, as hereafter fully explained. It is no doubt chiefly to these ascending currents that the heated ball in Experiment 1 owed its ascent to the surface; for if the heating took place in perfectly motionless cast iron, there seems no reason why the place of the sunken ball should change up to the moment of complete fusion\*.]

*Experiment 2.* Two parallelopipeds, each  $2'' \times 2'' \times 6''$ , were cast of close grey iron; one of these was placed cold upon the surface of a large ladle of liquid iron of like quality; the other was heated as hot as it would bear without distortion, viz. to nearly a bright yellow heat, in a forge-fire, and then placed upon the surface of the liquid metal. Both pieces floated, and, as nearly as could be judged, both to the same height above the liquid, namely 0.1808 in. The volume of the cold piece being 24 cubic inches, the ratio of the immersed to the emergent portions was as 9.6 to 1, the effective surface upon which the repulsive force could act in producing floatation being 12 sq. in. Assuming that the heated piece has been raised from  $60^\circ$  Fahr. (the temperature of the cold piece) to  $2000^\circ$  Fahr., and applying the mean coefficient of cubic dilatation as above given to this range of temperature, viz.  $2000^\circ - 60^\circ = 1940^\circ$  Fahr., we find that its volume was enlarged to 24.75 cubic inches, or  $= \frac{1}{3}\frac{1}{2}$  of the volume when cold; and taking the specific gravity of the cold piece to have been 7.17 (see *ante*), that of the hot piece would be reduced to 7.10; the effective repellent surface was slightly enlarged in the hot piece, and the immersed volume was to the emergent volume as 9.66:1. The buoyancy of the heated piece had been increased, or, more correctly, its *negative* buoyancy had been decreased, as compared with that of the cold piece, but yet it has sunk deeper into the liquid iron in proportion to their respective volumes. We may therefore be justified in concluding that the repellent force which kept both pieces afloat is diminished in energy in some proportion as the difference in temperature between the liquid metal and the piece floating upon it is diminished, and that where the liquid and the floating pieces are alike in quality of metal, both the negative buoyancy and the repellent force must both disappear at the instant that the floating piece itself becomes liquid by heat abstracted from the molten metal.

\* All passages printed in brackets take date from 20th December, 1874.

Mr. R. Mallet on the alleged Expansion

3. Two cylindric pieces of the same grey cast iron and of diameter ( $=2.375''$ ) were gently placed with their axes horizontal on the surface of the molten iron, the one being at  $60^{\circ}$  Fahr., the other at  $300^{\circ}$  Fahr.; they both floated with a segment of the cylinder emergent. The volume of either was 2.15 cubic inches, and the emergent was to the immersed as 1 to 4. The effective repellent surface in each case (or cylinder, below the horizontal diameter) was 18.65 sq. in.; but if we take into account the fact we have done, that the repellent force, whatever be its direction, is everywhere perpendicularly to surfaces of contact of the cylinder with the liquid, then the effective repellent surface here is only the difference between the immersed surfaces of the cylinder below and above the horizontal diameter, or 9.3 sq. in. From this we may perhaps conclude that the repellent force is mainly dependent upon the extreme upper parts of the cylinder, and the temperature between the liquid and the cold body, inasmuch as the augmentation in temperature of the latter of  $300^{\circ}$ , or about the whole range between solidity and fusion of the cast iron, produces a sensible alteration in the tendency to float of the pieces.

4. Three circular disks of the same grey cast iron, each of diameter  $2.375''$  in thickness, were provided each with a slender iron rod passing into the centre of one surface, so that by a hooked wire the disk could be gently laid upon the surface of the liquid iron of their own weight. The lower surface and edge of one disk were left as it came clean

Now the effective repellent surfaces are here those of the lower circles of the respective disks, and these surfaces are to each other in the ratio of 1 (the larger) to  $\frac{1}{4}$ . Whatever be the nature, therefore, of the repellent force, it seems to be proportionate to some function of the effective surface as already defined, and not to the immersed volume of the solid cast iron which floats upon a liquid less dense than itself.

In all these experiments the mass of the molten cast iron was large in proportion to the pieces placed upon it, and the surface was kept by careful skimming almost perfectly free from scoræ or oxide. A good deal of difficulty exists in observing the phenomena in such experiments as these, owing to the glare and heat of the molten metal. Whatever light these five experiments may throw upon the nature of the force which produces flotation, the subject must as yet be viewed as very incomplete. There are some facts of which no complete explanation can be offered without further experimental study; such as, for example, that a piece of cold cast iron which floats on liquid iron of its own quality if forcibly thrust to the bottom and rapidly and at once released, rises again rapidly to the surface with all the *appearance* of a *buoyant* body, which it certainly cannot be.

From what precedes, however, we may summarize as follows:—

If  $F$  be the force which keep the solid iron floating,  $B$  the buoyancy  $\pm$  of the solid piece, and  $R$  the repellent force, then, in the case of a piece floating upon molten iron of its own quality,  $B$  is always negative, and  $F = R - B$ , the value of  $R$  for any given case depending upon the *effective surface* of the solid, and that of  $B$  upon its volume, both being modified by the initial difference in temperature between the solid and liquid metals. In the case of the solid being placed on liquid cast iron differing in quality from it,  $B$  may be either positive or negative, and  $R$  still dependent upon the conditions already stated. Hence in any such case we may have

$$F = R - B \text{ or } = R + B.$$

These conditions kept in view may clear up many phenomena at first apparently anomalous.

[However feeble may be the ascending currents, above referred to, upon the floating disks in experiment 5, their effect must be viewed as proportionate to the lower surfaces, and therefore proportionate to the repellent force, and as possibly adding, though slightly, to its effect.]

The following experiments were made at the Royal Arsenal, Woolwich, with a view to ascertain whether any sensible expansive force could be recognized as due to the enlargement in volume by consolidation of a spherical mass of cast iron:—Two spherical bomb-shells, each of about 10" in diameter and 1"·5 in thickness, whose external orthogonal dia-

### Mr. R. Mallet on the alleged Expansion

been carefully taken when at atmospheric temperature (r.), were both heated in an oven-furnace. One of these was thus heated, but not to a *very* bright red, was permitted to cool again, and its final dimension when cold noted. The other was withdrawn from the oven when at a bright red heat, and was filled to a little above the inner orifice of the fuse-hole (line *a b*, fig. 3) with molten cast iron, the quality of this being dense mottled grey iron smelted at Elswick Works from the best ores, and used in the arsenal for casting projectiles. The orifice was closed by a screw-plug, which, however, did not reach the surface of the molten metal, and the whole surrounded by a sheet-iron screen to keep out the air, was allowed to cool. The dimensions being taken at intervals of half an hour as it cooled and continued until it became cold. The envelope was then cut through by a great circle at right angles to the axis passing through the centre of the halves of the sphere, the interior sur-

The object of heating and cooling the empty shell was to ascertain what amount, if any, of permanent enlargement it might suffer, it being a well-known fact that all solids of revolution of cast iron, and generally of all metals of sufficient rigidity, become permanently enlarged by being heated red-hot and permitted to cool. This arises from the fact that the outer *couches* of the solid (a sphere for example) are the first heated and expanded, and have to draw off more or less from the less-heated mass within. Tangential thrusts and radial tensions are thus produced in the material of the outer *couches* which disappear, or even become reversed, as the progress of heating reaches the interior of the mass; but in the subsequent cooling the entire train of forces is reversed, the exterior *couches* lose heat by dissipation first, and have to accommodate by tangential tensions their dimensions to the still hotter interior, the final result being that when the whole has cooled the dimensions are greater than before the solid was heated. A 32-lb. spherical shot, which is rather more than 6 inches in diameter, can be thus permanently increased  $\frac{1}{10}$  of an inch in diameter by a single heating. It is obvious that the increase will be much less in a spherical shell than in a solid sphere, and the less as

the shell is thinner\*. On inspecting the Table and curve fig. 5, it will be seen that the empty shell had its diameter thus permanently enlarged by 0.008 of an inch ; and had it been heated to as high a temperature as the filled shell, we may allowably conclude that this enlargement would have reached 0.01 of an inch. The filled shell has had its diameter increased by the decimal 0.11 ; and if we deduct from this the amount of permanent enlargement due to heating only, equal to that of the empty shell, we have the decimal  $0.11 - 0.01 = 0.10$ , which has to be otherwise accounted for. This shell was at a bright red heat visible in clear daylight when filled with the liquid iron, which occupied the spherical cavity and about 0.43 in height of that of the fuse-hole. The temperature of the shell visibly rose by the heat communicated from the liquid metal, and in 30 minutes after it was filled had attained its maximum, the surface being then at a bright yellow heat in daylight when the first measurement of enlarged diameter was made. The successive measurements were taken for orthogonal diameters in the direction normal to the fuse-hole by means of finely graduated steel beam calipers capable of being read to 0.002 of an inch or even less ; the dimensions set down in the Table are the means of each pair of orthogonal diameters. The shell was thus heated at the commencement, and before consolidation of its liquid contents had taken place to any considerable extent, to within probably  $200^{\circ}$  or  $300^{\circ}$  Fahr. of the temperature of the cast iron within. The shell and its contents are therefore at the commencement very nearly in the same condition as though the whole were a sphere of molten iron without any more or less rigid envelope, if such could exist. Reverting to what has been said above as to the train of forces called into play in a cooling sphere, let us consider what has taken place here. As the heat is dissipated from the exterior of the molten mass, being transmitted through the shell, one *couche* after another of the molten metal in contact with the inner wall of the shell consolidates, the thickness constantly advancing towards the interior, where the metal is still liquid. If each of these *couches* in consolidating expanded in volume, such expansion must conspire, with the contraction constantly going on by the abasement of temperature, to produce compression in the central and as yet unsolidified portion of the mass. If, on the contrary, each *couche* as it solidifies contracts in volume (and, as is the fact, by a larger coefficient of contraction for equal small ranges of temperature before and after solidification), then the effect must be that, after the solidified crust has attained a certain thickness and sufficient rigidity, the further progress of contraction of the central portions as they successively solidify must be met by their tending to draw off from the solidified shell, or, in other words, by a drawing-off from each other of the particles of that central portion of

\* For a more complete analysis of the complex strains brought into play by expansion and contraction in the heating and cooling of metallic solids of revolution, the author may refer to his paper "On the Coefficients  $T_e$  and  $T_c$  in large masses of Forged Iron," published in the Minutes of Proceedings Inst. C. E. London, vol. xviii. p. 299.

### Mr. R. Mallet on the alleged Expansion

h last solidifies. Now the latter is exactly what has happened of the exterior and first solidified crust, reaching about inwards from the interior of the shell, was found to have a specific gravity of 7.150 at 57° Fahr., while a portion taken close to the center had a specific gravity of only 7.037; and this specific gravity would have been still lower (or, in other words, the central part would have been still more "spongy") had it not been fed inwards a portion of the liquid iron which partially filled the portion so drawn down being estimated by the volume left at 0.400 of a cubic inch; so that but for this the weight of the central spongy sphere taken at 3" diameter would be reduced to 6.776.

If this central spongy mass of 3" diameter and of the last specific gravity to a density as great as that found for the exterior, namely 7.150, the sphere of 3" diameter would be reduced to 6.776; and it is easy to see that in that case the external weight of the whole sphere of metal and of the containing shell would be in a corresponding proportion, and that thus the final weight of the shell would have returned to what they were at the beginning, less the permanent enlargement, as measured by that of the metal. If there existed, on the other hand, any sensible expansion of the metal in consolidating, not only would a central spongy mass be impossible and the central be the densest part of

1. Between the hours 1.50 and 2.45 but one caliper measurement was made, namely at 2.15, and upon this one measurement both the existence and the amount of this anomalous part of the curve depend. An error in this single caliper measurement amounting to 0.006 of an inch was sufficient to have produced it; and as the limit of reading of the beam calipers was to a limit of 0.002 or possibly 0.001 of an inch, a mistake in the measurement at 2.15, or a misreading of only the decimal .004 or .005 at most, is sufficient to account for the anomaly.

2. The hump on the curve does not necessarily indicate expansion, and from the early time of its occurrence, viz. only 1 hour 25 minutes from the commencement of cooling, it seems highly improbable that it could arise from partial expansion then commencing, while as yet a very large proportion of the entire mass must have been still liquid.

3. If this anomalous part of the curve were really due to expansion, it must have much more extensively affected the lower prolongation of the curve, and have shown itself there in a form that would have unmistakably declared its origin.

4. On examining the curve fig. 5 a slight anomaly may be remarked in the rate of contraction of the empty shell, due no doubt to some slight error in the third measurement, or that at 1.50 P.M. In this instance it would be impossible to ascribe the anomaly to expansion of any sort.

The dotted line A (fig. 4) may therefore be viewed as completing the curve of contraction.

The curve fig. 6, representing the volume of the filled shell at successive epochs of cooling, is deduced from the Table (p. 221), assuming the successive volumes to be proportionate to the cubes of the diametric measurements, the curve being a mean drawn through the several points of observation.]

The supposition upon which Messrs. Nasmyth and Carpenter's theory rests may be divided into two distinct propositions.

1st. That cast iron is of greater density in the molten than in the solid state.

2nd. That cast iron in the act of consolidation expands in volume. These propositions are not identical, although the second is involved in the first. The first proposition has been already disposed of, and the last recorded experiments appear conclusively to disprove the second.

The phenomena described by Messrs. Nasmyth and Carpenter, and their explanation of the circulating currents observable in large and nearly cylindrical ladles of molten iron, appear at first sight so confirmatory of their views as to the greater density of cast iron in the molten than in the solid state, that it seems necessary here to present the true explanation of the facts, which, so far as they are here relevant, may be best given briefly in the words of these authors:—

“When a ladle of molten iron is drawn from the furnace and allowed

Mr. R. Mallet on the alleged Expansion

the thin coat of scoria or molten oxide which forms on the metal is seen, as fast as it forms at the circumference be swept by active convergent currents towards the centre, and accumulates in a patch. As the fluid metal parts with some of the ladle gets hot by absorbing it, this remarkable surface becomes less energetic." This arises from "the expansion of the molten mass which is in contact with the comparatively sides of the ladle, which sides act as the chief agent in dispersing the melted metal; careful observation will show that the motion is the result of an upward current of the metal around the circumference of the ladle, as indicated by the arrows A, B, C in the sectional drawing Fig. 7; the figure is essentially the same [as in the authors]. "The motion of the metal can be seen at the rim of the ladle, where it is directed into the central direction, and thus an elevatory appears as shown in the figure. We assign to this any effect of expansion and

Fig. 7.

molten mass and determine the direction of its currents ; and it will be obvious, on inspecting the figure, that these currents will be most powerful round the outer circumference of the mass, where each unit of its top surface has a larger proportion of lining in proximity to it than at the central parts of the mass, where downward currents are the necessary consequence of those produced upwards at the circumference. The organic matters mixed with the lining are carbonized, and give forth the elements of water as well as nitrogen. The clay, which is a hydrous silicate of various earthy bases, gives forth its water and some of the oxygen of the peroxide of iron which most clays contain. More or less carbonate of lime is almost always interspersed, and this gives forth carbonic acid and water. The gases thus streamed forth act mechanically by their ascent and also chemically upon molten iron, the water being decomposed, oxidizing portions of the iron and forming scoriæ, which is again more or less reduced by contact of the hydrogen and nitrogen when the latter is present. These rapid combinations and decompositions are no doubt the main cause of those singular vermicular startings referred to by Messrs. Nasmyth and Carpenter, which are familiar to every iron-founder, but which are entirely distinct from the ascending and descending currents due to the ascent of the evolved gases. That this is the true explanation is supported by the following facts :—1. After a large ladle has stood full of molten metal for some hours, and time has been given thus for the whole of the gaseous contents of the lining to be driven off, the ascending and descending currents cease to be perceptible, and if any currents at all can be discerned they are in the opposite directions. 2. If, after this, such a ladle be emptied of its contents, the lining remaining untouched and only coated with a thin shell of adherent cast iron [and oxides and silicates of iron], and the ladle being again filled with molten iron, no such currents as at first are produced in the molten mass, the lining having been previously exhausted of its gases and vapours. That the currents described by Messrs. Nasmyth and Carpenter are *not* due to dissipation of heat from the mass through the sides of the ladle is evident from the following considerations :—

A 10-ton ladle, which is about  $4\frac{1}{2}$  feet by 3 feet in depth, loses heat so slowly that after standing for six hours the molten metal is still fluid enough to make castings. Let us suppose it filled into the ladle at a temperature of  $2800^{\circ}$  to  $2900^{\circ}$  Fahr., and that after six hours it is still  $200^{\circ}$  above the temperature of solidification of cast iron, or at  $2600^{\circ}$ . The molten mass has thus lost  $300^{\circ}$  of heat in 360 minutes, or  $\cdot 0138$  of a degree per second. We may assume this at any instant as representing the difference in temperature between two vertical columns, one at the centre and the other at the circumference of the molten mass. The linear dilatation of cast iron for one degree of Fahrenheit being  $0\cdot 0000111$ , as deduced from its total cubic dilatation between  $60^{\circ}$  Fahr. and the temperature of fusion at which it was poured into the cone, as given in this

Mr. R. Mallet on the alleged Expansion

...ing the depth of the colder of these columns, whether circumference or not, to be, as stated, 36", that of the hotter 36.0000005514, and the difference between these two forces which alone can produce circulating currents in the masses of temperature due only to cooling. This is equally to be the colder column that is dilated, as supposed by Nasmyth and Carpenter, or the hotter one, as is the fact. And from the viscosity of molten cast iron, it is perfectly obvious that the circulating currents referred to by Messrs. Nasmyth and Carpenter are due to so insignificant a cause.

Attention, or careless interpretation of the many and somewhat contradictory conditions thus seen to be involved in the cooling of a mass of iron, and its consequent loss of heat from its exterior, has caused many serious misapprehensions on the part of experimenters as to the supposed expansion of metals in volume when consolidating. Thus, even in the case of iron, it has been supposed a conclusive proof of its expansion during cooling in an open crucible exudes from its interior in the form of cauliflower-like excrescences; but although the author has never seen any or affirm any thing as to expansion being a fact in the case of iron, it is nevertheless obvious that such excrescences might be produced by the grip of the crucible itself, or even of the exterior metal already solidified contracting upon and so squeezing out of the still liquid interior.

of the facts, is, that when a very thick iron mould of this sort is suddenly heated by pouring molten iron into its interior, as the heat abstracted from the latter can only pass into the material of the mould at a rate determined by its conductivity, so the interior part rapidly becomes raised to a temperature enormously higher than the exterior portions, which for a time remain almost cold. The expanded interior walls of the mould push inwards as towards the points of least resistance, and so actually diminish the capacity of the mould for a time, the inner surfaces of which press upon the consolidating crust of metal within it, and so squeeze out in part its liquid contents, just as water might be squeezed from an india-rubber bottle\*.

It seemed desirable to obtain some experimental results in reference to the objects of this communication with lead. It has never, so far as the author is aware, been even suggested that this metal expands in consolidating. Its coefficient of dilatation by heat is enormously greater than that of cast iron, being, according to the determination of Lavoisier and Laplace, between  $32^{\circ}$  and  $212^{\circ}$  Fahr.  $=0.000474$  of its volume for one degree Fahr.; so that, taking its fusing-point at  $617^{\circ}$  (Rudberg), and assuming the coefficient constant for the entire range from  $60^{\circ}$  to  $617^{\circ}$  (which is much below the truth), its dilatation when in fusion would be  $=0.0264$  of its volume, and the specific gravity of lead at  $60^{\circ}=11.36$ ; that of liquid lead must be *below* 11.07. Indeed this enormous amount of dilatation is impressed upon any observer who sees the rate at which the lead in casting a common bullet sinks into the neck of the mould, and the comparatively large cavity which always exists in the ball when cut in two. From its low temperature of fusion and the suddenness with which lead passes from the solid to the liquid state without any phase of intermediate viscosity, and only a brief one of crystalline brittleness, and the facility with which its surface can be kept free from dross or oxide, this metal presents a "crucial" example for experiment in reference to our subject.

The following experiments, by the kind permission of Messrs. Pontifex and Wood, London, were made at their works:—

1st. Upon the surface of a large pot of melted lead, the temperature

\* The enormous disparity in temperature between the interior and the exterior *couches* of a very thick spherical or cylindrical iron mould is only partially shown by Biot's expression,

$$\log y = \log Y - \frac{x}{M} \sqrt{\frac{b}{a}},$$

for the distribution of temperature along a bar heated at one extremity; for in the case here before us, as in that of all forces radiating from a centre, the temperature at any given point, and quite independent of any question of conductivity, varies inversely as the square of its distance from the centre. If a unit in volume situated in any point of a radius lose as much heat as will lower its temperature  $1^{\circ}$ , that heat, when transmitted to double the distance along the radius, can only raise the temperature of a unit in volume there by 0.25 of  $1^{\circ}$  having been diffused amongst four units of volume. (See Biot, 'Traité de Physique,' and Mallet, 'Trans. R. I. A.,' 1856.)

Mr. R. Mallet on the alleged Expansion

estimated at from  $750^{\circ}$  to  $880^{\circ}$  Fahr., the half of a large melted lead, being a semicylindrical bar of about  $5'' \times 2\frac{1}{2}''$  long, was gently laid down horizontally; it immediately sank to the bottom and there remained. When about half its volume was fused, the unfused portion was drawn up to the surface and at once sunk to the bottom again.

A piece of such lead was cast, weighing  $17\frac{1}{2}$  lbs., diameter about 2 inches, and was put into an empty hand-ladle, which was gently placed upon the surface of the pot of melted lead; the ladle was depressed sufficiently to sink into the lead, and being left free was carried to the bottom of the pot by the impetus to produce a sensible blow of the exterior of the bottom of the pot.

A circular disk of about 1.25 inch in thickness, being laid upon the surface, after a moment's hesitation slowly went to the bottom. A larger disk of 6" diameter, by rather less than an inch in thickness, remained a few seconds longer on the surface and then sunk to the bottom. Both disks, while they floated, had their top surfaces but slightly elevated above that of the liquid lead. One of the disks was pushed into the liquid lead vertically and edgeways, at once sinking to the bottom.

Two disks, each 6" diameter, the one 0.57 inch and the other 0.4 inch in thickness, being gently laid flat upon the surface of the melted lead, floated, and with an emergent portion sensibly greater than

I proceed to some remarks upon the experiments referred to at the commencement of this paper, and quoted by Messrs. Nasmyth and Carpenter, as to the floating of pieces of solidified iron furnace-slag upon the same slag when in the liquid state. It is a fact that blast-furnace slags cooled below the point at which they become rigid do very generally float upon the same slag in its molten state. It is equally true that the basic silicates which constitute the chief part of terrestrial volcanic lavas float upon the surface of these when molten. But these admissions do not suffice in any degree to support the conclusion deduced by Messrs. Nasmyth and Carpenter, that basic silicates, whether as furnace-slugs or lavas, are denser in the molten than in the solidified state, nor that these bodies in the act of solidification expand in volume or decrease in density in any manner, irrespective of the formation or enlargement of cavities or gas-bubbles within them. The experiments of the author upon the total contraction of iron furnace-slugs for the entire range of temperature between that of the blast-furnace and the atmosphere, made at the Barrow Iron-Works, and fully described in the author's paper on "The Nature and Origin of Volcanic Heat and Energy," printed in Phil. Trans. for 1873, leave no doubt as to the following facts:—

1st. That the density of such slags at 53° Fahr. is to their density when molten and at the temperature of the blast-furnace as 1000 : 933, or, taken at the melting-point of slag, as 1000 to 983—molten slag being thus very much less dense than the same when solidified.

2ndly. That no expansion in volume whatever occurs in such slags at or near the instant of solidification.

The experiments of the author above referred to were made by filling cast-iron slightly conical moulds with the slag run direct from the blast-furnace, and permitted to consolidate and cool therein, by which perfectly solid slightly conical blocks were obtained. From the method employed, and the very large scale upon which these experiments were conducted, it is *impossible* that any expansion in volume at or near the point of consolidation, if even of a very minute amount, could have occurred and yet have escaped notice\*. It is only necessary for the author here to point out that the floating of crusts of slag or lava is *not* due to the cause assigned by Messrs. Nasmyth and Carpenter; nor is it his intention to enter at any length into what are the causes of such floating when it occurs.

The following remarks, however, may be made:—It is impossible to obtain a moderate-sized fragment of solidified slag or lava free from air-bubbles, and from involved or superficial cavities, which tend to float the mass when thrown upon its own material in the melted state. Those who have attentively watched large volumes of slag issuing from the blast-furnace are aware that it comes forth carrying with it a large

\* [For the proofs of which in detail the author begs to refer to his paper at length, Phil. Trans. 1873.]

Mr. R. Mallet on the alleged Expansion

ous matter minutely diffused, which is pretty readily separated by a white vaporous cloud floating thinly over the surface; if the slag be cooled rapidly, the gaseous or vaporiferous matter become confined and render the mass vesicular, while cooled slowly, and with a free surface for the escape of these, it becomes more solidly, often as solidly as a block of granite\*.

Of the buoyancy that is produced by the vesicularity of slags, it is highly probable that relatively cold and solid slag, whose buoyancy is negative, may yet float on molten slag, whose buoyancy is positive, in virtue of that same repellent force which, as we have seen, acts under like conditions in the case of metals.

As to acid silicates, or slags analogous to glass (which, however, is not referred to by Messrs. Nasmyth and Carpenter), the author has verified the results given in his paper (Phil. Trans. 1873). These circumstances attending the production and destruction of "Rupert's drops," incontestably prove that these silicates are denser in the molten than in the solid state, and that the change takes place suddenly at or near the instant of consolidation.

It is more than once heard the opinion expressed by those who work blast-furnaces, that their slags do expand in consolidating, and the interpretation of the following frequently occurring circumstance will confirm the large parallelopipeds of slag (5 to 6 feet square by

into any detail to prove that the phenomena are due to the contraction of the already solidified exterior upon the unyielding interior of the mass; the former becoming fractured by its own grip, and its material being highly elastic, often yields with apparently explosive violence like a suddenly broken spring (see fig. 9, which shows the appearance of one of these fractured and slowly exuding blocks).

[The following remarks may be made, in addition to those preceding, in contravention of the supposed expansion of slags or lavas in consolidating. It is well known that masses of mud when dried by the sun crack, the fissures penetrating nearly perpendicular from the surface and separating into more or less symmetrical prisms. Blocks of starch after desiccation present similar phenomena, which are also frequently seen exemplified by the uppermost beds of argillaceous limestone (or calp) of Ireland when first laid bare from its detrital covering. In all these cases there can be no doubt that the phenomena are due to the shrinkage of the mass in drying. But shrinkage or contraction by cooling and consolidation ought to present us with like results; and these we see actually manifest in the splitting-up of basalt into columnar prisms whose long axes are always found perpendicular to the surface by which the heat of the mass was dissipated. Such columnar separation is not confined to basalt; instances of it are abundant in lavas of every age, the surfaces of the prisms in these being sometimes straight, sometimes curved. Although much remains yet to be investigated before all the circumstances attending the splitting-up of masses of basalt or lava can be said to be fully understood, yet enough is already known and clearly explained to make it certain that it is due to *contraction* of these materials as they cool; and that this form of splitting-up is wholly incompatible with that of any fissuring that could arise from the refrigeration of a mass the volume of every part of which expanded in consolidating.]

As in what precedes the hypothesis upon which the lunar volcanic theory of Messrs. Nasmyth and Carpenter rests is proved to be without foundation, it seems needless to enlarge upon the incongruities and contradictions which the theory itself presents when fairly applied to such knowledge as we have of the volcanic features of the moon, or still more when applied, as it must be were it true, to those of our earth, [assuming the materials of our earth and satellite analogous in their physical and chemical properties—an assumption made by these authors throughout their work, though without any attempt to support it by proof].

In concluding this paper, the author has to express his thanks for the liberality and assistance afforded him by Messrs. Maudslay, Sons, and Field, who showed their just appreciation of the true value of scientific research by assisting in this inquiry of an abstract character, and without apparent technical applicability. He also has to thank Mr. E. Duncan, of the above firm, for his personal aid and cooperation. He also has to express his thanks for the valuable assistance so readily

rest of two of the questions started and partly dis-

believe it will prove that the truth lies between two extreme views. That the *Globigerinæ* live on the bottom only is a position clearly no longer tenable; but that they live and multiply in the upper waters only, and only sink to the bottom after death, seems to me a position no more tenable than the preceding: and I shall now adduce the evidence which appears to me at present to justify the conclusion (I refrain from expressing myself more positively, because I consider the question still open to investigation), that whilst the *Globigerinæ* are pelagic in an earlier stage of their lives, frequenting the upper stratum of the ocean, they sink to the bottom whilst still living, in consequence of the increasing thickness of their calcareous shells, and not only continue to live on the sea-bed, but probably multiply there—perhaps there exclusively.

That there is no *à priori* improbability in their doing so, is proved by the abundant evidence in my possession of the existence of Foraminiferal life at abyssal depths. The collections made during the 'Porcupine' Expeditions of 1869 and 1870 yielded a large number of those *Arenaceous* types which construct their "tests" by the cementation of sand-grains only to be obtained on the bottom; and these were almost the only Foraminifera, except *Globigerinæ* and *Orbulinæ*, which came up in the 2435 fathoms dredging. Again, many Foraminifera, both arenaceous and shelly, were brought up from great depths, attached to shells, stones, &c., that must have lain at the bottom. Further, among the "vitreous" Foraminifera, the most common deep-sea types, except those of the Globigerine family, were *Cristellarians* with shells so thick and massive as to be (it may be safely affirmed) incapable of being floated by the animals which form them; while among the "porcellanous" Foraminifera, the *Biloculinæ* and *Triloculinæ* were equally distinguished by a massiveness of shell, which seemed to forbid the idea that they could have floated subsequently to that stage of their lives in which this massiveness had been acquired.

Of the existence of living *Globigerinæ* in great numbers in the stratum of water immediately above the bottom, at from 500 to 750 fathoms depth, I am able to speak with great positiveness. It several times happened, during the Third Cruise of the 'Porcupine' in 1869, that the water brought up by the water-bottle from immediately above the *Globigerina*-ooze was quite turbid; and this turbidity was found (by filtration) to depend, not upon the suspension of amorphous particles diffused through the water, but upon the presence of multitudes of young *Globigerinæ*, which were retained upon the filter, the water passing through it quite clear. The thin shells of these specimens, exhibiting very distinct pseudopodial orifices, contrasted strongly with the larger and thicker shells of the specimens brought up by the sounding-apparatus from the bottom immediately beneath, in which the shells are thick and those orifices obscure. It is obvious that if this extraordinary abundance of Globigerine life in the bottom-water was the result of subsidence from

ab-surface stratum, and was merely preparatory to the shells on the sea-bed, there should have been a correspondence and condition between the floating shells and those at the bottom immediately beneath them; whereas no contrast is complete, the impression given by the superficial aspects presented having been fully confirmed by subsequent examination.

Thomson and Mr. Murray, who notice this contrast, are aware of the death of the shells which have subsided to the bottom—unaware that the observations of Dr. Wallich, with which they are in entire accordance, leave no reasonable ground for the consequence of their continued life. For it is clearly shown by thin transparent sections of the thick-shelled *Globobuccina* which needs a dexterity only to be acquired by long practice, which is much facilitated by an ingenious device invented by Dr. Wallich (\*), that the change of external aspect is due to the formation of a new deposit (a rudiment of the "intermediate skeleton" of the *Ammonifera*) which is formed, after the full growth of the animal has been attained, upon the outside of the proper chamber—thus completely masking its pseudopodial orifices, that Prof. Huxley attributes to their existence. This deposit is not only many times thicker than the original chamber-wall, but it often contains flask-shaped processes on the exterior, and containing sarcodæ prolonged into

sheet of my 'Introduction to the Study of the Foraminifera' comprising the Globigerine family passed through the press, but which I have myself subsequently confirmed in every particular) it seems an almost inevitable inference that the subsidence of the *Globigerinæ* to the bottom is the consequence, not of their death, but of the increasing thickness and weight of their shells, produced by living action. As long as the number of segments continues to increase, the carbonate of lime separated by the sarcodic body from the circumambient water goes to form the walls of additional chambers; but when this chamber-formation ceases (which usually occurs when the shell consists of either 12 or 16 segments), it is applied to thicken the walls of the chambers already formed; and from the rapid subsidence of the *Globigerinæ* taken up from the sea-bottom when thrown into a jar of sea-water, it seems to me inconceivable that they can be floated by their animal inhabitants when once the exogenous deposit has attained any considerable thickness.

That the *Globigerinæ* which have subsided to the bottom continue to live there, is further indicated by the condition of the sarcodic contents of their shells. In any sample of *Globigerina*-ooze that I have seen brought up by the dredge or the sounding-apparatus, part of the shells (presumably those of the surface-layer) were filled with a sarcodic body corresponding in condition with that of Foraminifera known to live on the sea-bed, and retaining the characteristic form of the organism after the removal of the shell by dilute acid. As Dr. Wallich pointed out ('North-Atlantic Sea-bed,' p. 139), the sarcodic of these is viscid, and inclined to coalesce again when crushed; the shell has a vivid but light burnt-sienna colour, and sarcodic bosses, like retracted pseudopodia, are distinguishable upon its exterior. The only misgiving I ever had in regard to the living condition of the *Globigerinæ* presenting these characters, was caused by the absence of any pseudopodial extensions; and this source of doubt has been now removed by the statement of Prof. Wyville Thomson, that no pseudopodia have ever been observed by Mr. Murray to be put forth by the *Globigerinæ* captured in surface-waters.—In the same sample will be found shells distinguishable from the preceding by their dingy look and greyish colour, by the want of consistence and viscosity in their sarcodic contents, and by the absence of any external sarcodic investment; these are presumably dead. Other shells, again, are entirely empty; and even when the surface-stratum is formed of perfect *Globigerinæ*, the character of the deposit soon changes as it is traced downwards. "The sediment," as was correctly stated by Prof. Wyville Thomson, "gradually becomes more compact; and a slight grey colour (due, probably, to the decomposing organic matter) becomes more pronounced, while perfect shells of *Globigerina* almost disappear, fragments become smaller, and calcareous mud, structureless and in a fine state of division, is in greatly preponderating proportion" ('Depths of the Sea,' p. 410). These facts seem to me to mark very strongly the

between the living surface-layer and the dead sub-surface. We know that there is nothing in the condition of the Deep to prevent or even to retard the decomposition of the bodies of *Globigerinæ*. We know that oxygen is present in even to its abyssal depths, in sufficient proportion for the animal life; and what suffices for this, must be adequate for the decomposition of organic matter. There is, moreover, a demonstration of the undecomposed condition of the sarcodæ *Globigerinæ* of the surface-layer, in the fact that they serve as food for higher animals which live on the same bottom. This was pointed out by Dr. Wallich, who found that the contents of the *Ophiocomæ* brought up in his 1260 fathoms sounding, consisted of a number of fresh-looking *Globigerinæ* more or less broken up into amorphous particles, and a few oil-globules ('North-Atlantic', p. 145). And I have subsequently verified his statement in other cases\*.

It is clear, from the foregoing facts, that the *onus probandi* rests on those who maintain that the *Globigerinæ* do not live on the surface. Their proof is altogether wanting. The most cogent evidence in favour of that proposition would be furnished by the capture, in the upper waters, of the large thick-shelled specimens which are generally known as having been brought up from the sea-bed. The discovery of such specimens would only prove that even in this

that the "white mud" of the Levant is mainly a Foraminiferal deposit; I found a similar mud covering the bottom along the Tripoli coast; Mr. J. Gwyn Jeffreys has dredged Foraminifera in abundance in the Bay of Spezzia, Captain Spratt in the Ægean, Oscar Schmidt in the Adriatic, and I myself at various points in the Western basin along the northern coast of Africa. That Foraminifera, especially *Globigerina*, abound in its surface-water at Messina, is testified by Haeckel in the passage cited by Prof. Wyville Thomson; and when it is considered how large an influx of Atlantic water is constantly entering through the Strait of Gibraltar, and is being diffused throughout the Mediterranean basin, and how favourable is its temperature-condition, it can scarcely be doubted that if the doctrine now upheld by Prof. Wyville Thomson were correct, the deposit of *Globigerina*-shells over the whole bottom-area ought to be as abundant as it is in the Atlantic under corresponding latitudes. Yet I found the deeper bottoms, from 300 fathoms downwards, entirely destitute of *Globigerina* as of higher forms of Animal life; and this was not my own experience only, but was also that of Oscar Schmidt, who made a similar exploration of the Adriatic. In my first visit to the Mediterranean, in the 'Porcupine' (1870), many hundredweight of the fine mud brought up by the dredge from great depths in the Western basin were laboriously sifted, and the siftings carefully examined, without bringing to light more than a stray drift-shell here and there. And in my second visit, in the 'Shearwater' (1871), I examined all the samples of bottom brought up by the sounding-apparatus from great depths in the Eastern basin, with the same result—giving all the more care to this examination, because Capt. Nares (probably through not having kept separate in his mind the results of the deeper and of the shallower soundings which he had previously made in the Mediterranean) assured me that I *should* find minute shells imbedded in the mud.

I can see no other way of accounting for the absence of *Globigerina*-ooze from the bottom of the Mediterranean, save on its shallow borders, than by attributing it to the unfavourable nature of the influences affecting the *bottom-life* of this basin: that is to say, the gradual settling-down of the fine sedimentary deposit which forms the layer of inorganic mud everywhere spread over its deeper bottom, and the deficiency of oxygen and excess of carbonic acid which I have shown to prevail in its abyssal waters giving them the character of a stagnant pool—these influences acting either singly or in combination.

Another fact of which Prof. Wyville Thomson is fully cognizant, and to which he formerly attached considerable importance as indicative of the *bottom-life* of the *Globigerina*, is unnoticed in his recent communication: I refer to the singular limitation of the *Globigerina*-ooze to the "warm area" of the sea-bed between the North of Scotland and the Faroe Islands. It will be recollected by those who have read my 'Lightning' and 'Porcupine' Reports on the exploration of this region,

whole upper stratum, from the surface to a depth of from  
ms, has the temperature of the warm flow coming up  
and whilst this temperature falls so gradually in the  
with increase of depth as to be still as high as 43° Fahr.  
0 fathoms, it falls so suddenly in the "cold area" be-  
00 fathoms, that the whole of its deeper stratum has a  
32°, the bottom temperature descending in some parts  
on this "cold area" I never found a single *Globigerina*,  
sting of sand and gravel, and the Foraminifera brought  
almost exclusively those which form arenaceous tests.  
," on the other hand, is covered with *Globigerina*-ooze to  
th, its surface stratum being composed of perfect shells  
le, whilst its deeper layers are amorphous. Near the  
two areas, but still within the thermal limit of the  
and *Globigerina*-ooze are mingled -this being peculiarly  
"Holténia-ground," which yielded a large proportion  
worthy captures in this locality. Now if the bottom-  
ident on the life of the surface-stratum, why should  
complete absence of *Globigerina*-ooze over the "cold area,"  
the surface-stratum being everywhere the same? I  
erly disposed to attribute it to the depression of bottom-  
t as it has now been proved by the 'Challenger' obser-  
atlantic, that *Globigerina*-ooze prevails over areas whose  
is but little above 32° this explanation can no longer

here (according to him) has a depth of 700 fathoms; and this very striking example of want of conformity between the surface-fauna and the bottom-deposit consequently remains to be accounted for on his hypothesis.

The other of Prof. Wyville Thomson's principal conclusions, as to which I have rather a suggestion to offer than an objection to take, relates to the origin of the "red clay" which he found covering large areas in the Atlantic, and met with also between Kerguelen's Island and Melbourne. Into this red clay he describes the *Globigerina*-ooze as graduating, through the "grey ooze"; and he affirms this transition to be essentially dependent on the depth of the bottom. "Crossing," he says "from these shallower regions occupied by the ooze into deeper soundings, we find universally that the calcareous formation gradually passes into, and is replaced by, an extremely pure clay, which occupies, speaking generally, all depths below 2500 fathoms, and consists almost entirely of a silicate of the red oxide of iron and alumina. . . . . The mean maximum depth at which the *Globigerina*-ooze occurs, may be taken at about 2250 fathoms; the mean depth at which we find the transition grey ooze is 2400 fathoms; and the mean depth of the red-clay soundings is about 2700 fathoms. . . . . We were at length able," he continues, "to predict the nature of the bottom from the depth of the soundings with absolute certainty for the Atlantic and the Southern Sea." And from these data he considers it an indubitable inference "that the red clay is essentially the insoluble residue, the ash, as it were, of the calcareous organisms which form the *Globigerina*-ooze after the calcareous matter has been by some means removed." This inference he considers to have been confirmed by the analysis of several samples of *Globigerina*-ooze, "always with the result that a small proportion of a red sediment remains, which possesses all the characters of the red clay." Prof. Wyville Thomson further suggests that the removal of the calcareous matter may be due to the presence of an excess of carbonic acid in the bottom-waters, and to the derivation of this water in great part from circumpolar freshwater ice, so that, being comparatively free from carbonate of lime, its solvent power for that substance is greater than that of the superjacent waters of the ocean. He might have added probability to his hypothesis if he had cited the observations of Mr. Sorby as to the increase of solvent power for carbonate of lime possessed by water under greatly augmented pressure\*.

Greatly struck with the ingenuity of this hypothesis, I turned to Prof. Wyville Thomson's tabular statement of the facts in detail; and must own to a great feeling of surprise at the want of conformity of these details with the assertions of universality and certainty of prediction which I have italicized in the above extracts. Thus in the deepest sounding in the whole Atlantic (that of 3875 fathoms, taken on the

\* Proceedings of the Royal Society, vol. xii. p. 538.

Thomas to Bermuda), as well as in the next two soundings of 2800 fathoms respectively (the average of the three soundings), the bottom was "grey ooze;" whilst in the next three soundings of 2850, 2700, and 2600 fathoms respectively (the average being 2716 fathoms, or nearly 400 fathoms less than the previous soundings), the bottom was of "red clay." Between Bermuda and the Azores there were six successive soundings between 2700 and 2800 fathoms in which the bottom was "grey ooze."

It is, however, to be observed, that no constant relation exists between depth and the nature of the bottom. If not only eight ordinary soundings whose average was almost exactly 2800 fathoms, but the extraordinarily deep sounding of 375 fathoms, gave a bottom of "grey ooze," it surely can be considered a well-ascertained fact that wherever the depth increases from 2600 fathoms, the modern chalk formation of the Atlantic passes into a clay."

The "red clay" had the character of an ordinary river-silt, and was quite conformable to my Mediterranean experience to regard it as a material (as Mr. Thomson himself was at first disposed to do) in the nature of a deposit derived from the land, diffused through the ocean-water by the action of the wind blowing down over particular areas, to which it might be determined by the prevalent direction of the bottom-flow, which would in its turn depend upon the ridge-and-valley conformation of the bottom. The presence of a small proportion of this material in the

occupied by mineral deposit, which, when the shell has been dissolved away by dilute acid, presents a perfect internal cast of its cavities. By the application of this method to Mr. Beete Jukes's Australian dredgings, my coadjutors, Messrs. W. K. Parker and T. Rupert Jones, obtained a series of internal casts of most wonderful beauty and completeness, on which I have based my interpretation of the organic structure of *Eozoon Canadense*. Having myself examined in the same manner a portion of the Foraminiferal sand dredged by Capt. Spratt in the *Ægean* (kindly placed in my hands by Mr. J. Gwyn Jeffreys), I have found that it yielded a great variety of these beautiful models, not only of the bodies of Foraminifera, but also of the sarcodic network which interpenetrates the calcareous network of the shell and spines of *Echinida*\*.

Alike in Mr. Jukes's and in Capt. Spratt's dredgings, some of these casts are in *green* silicates and some in *ochreous*, corresponding precisely to the two kinds of fossil casts described by Prof. Ehrenberg. The difference I presume to depend upon the degree of oxidation of the iron; but as these casts are far too precious to be sacrificed for chemical analysis, I cannot speak with certainty on this point.

As it is only in certain limited areas of the sea-bottom that this replacement of the sarcodic bodies of *Foraminifera* by mineral deposit is met with, it has always seemed to me next to certain that there must be some peculiarity in the composition of the sea-water of those areas (produced, perhaps, by the outburst of submarine springs highly charged with ferruginous silicates) which gives to them a capability that does not exert itself elsewhere; and this now seems yet more probable from the circumstance that, notwithstanding the vast extent over which the 'Challenger' soundings and dredgings have been prosecuted, only two or three cases of the kind have been noted—those, namely, of the "greenish sands" brought up from 98 and 150 fathoms in the region of the Agulhas Current and in one or two other localities. It is a fact of peculiar interest, moreover, that the calcareous shells should have here disappeared, just as they have done in ordinary green sand; and this, too, although the depth was so small as altogether to forbid the idea that their disappearance is due to any solvent process brought about by the agencies to which Prof. Wyville Thomson attributes the removal of the calcareous deposit generated by Globigerine life.

Now in the residue left after the decalcification of Capt. Spratt's dredgings, I noticed a number of small particles of *red clay*, some of them presenting no definite shape, whilst others approximated sufficiently closely in form and size to the green and ochreous "internal casts" to induce me to surmise that these also had been originally deposited in the chambers of Foraminifera—their material being probably very nearly the same,

\* Of these I hope to be able, ere long, to give a detailed account, in illustration of the similar models of the animal of *Eozoon* obtained by the decalcification of its serpentine lamellæ.

Sea-bottom procured by H.M.S. 'Challenger.' [Feb. 4,

the Foraminiferal shells whose internal casts formed the Greensand deposit of the Cretaceous epoch, must remain for the present an open question\*.

II. "Report to the Hydrographer of the Admiralty on the Cruise of H.M.S. 'Challenger' from July to November 1874." By Prof. WYVILLE THOMSON, F.R.S., Director of the Civilian Scientific Staff on Board. Received January 4, 1875. (Published by permission of the Lords of the Admiralty.)

H.M.S. 'Challenger,' Hong Kong.

The 'Challenger' left Port Nicholson on the 7th of July, 1874, and proceeded under sail along the east coast of New Zealand. On the 8th we rounded and trawled in 1100 fathoms, lat.  $40^{\circ} 13' S.$ , long.  $177^{\circ} 43' E.$ , with a bottom-temperature of  $2^{\circ} C.$  and a bottom of soft greenish ooze. Many animals were brought up by this trawl resembling closely those which we had taken at a corresponding depth in other portions of the southern sea. On the 10th we again trawled and sounded in 700 fathoms about 40 miles to the east of East Cape.

We then continued our course northwards towards the Kermadec Islands, and on the 14th we took our usual series of observations midway between Macauley and Raoul Islands in the Kermadec group. At this station we trawled at a depth of 630 fathoms; and we were greatly struck with the general resemblance between the assemblage of animal forms brought up in the trawl and the results of a good haul in about the same depth off the coast of Portugal or North Africa. Among the more interesting objects were a very large and splendid specimen of a Hexactinellid sponge allied to *Poliopogon*, several other fine sponges referred to the same group, and three or four examples of two species of *Pentacrinus* new to science, resembling generally *P. asteria*, L., from the Antilles. We trawled on the following day in 600 fathoms, 45 miles to the north of Raoul Island, with nearly equal success. On the evening of Sunday the 19th we arrived at Tongatabu and called on the principal missionary, Mr. Baker, from whom we received every possible attention during our short stay. After spending two days in visiting different parts of the island, we left Tongatabu on the 22nd of July, and after taking a few hauls of the dredge in shallow water we proceeded towards Kandavu in the Fijis. On the 24th we stopped off Matuku Island and landed a party of surveyors and naturalists; and while they were taking

\* It is due to Prof. W. C. Williamson to point out that, in the Memoir already referred to, he indicated the probability "that many of our European Greensands, and other siliceous strata, however barren of such structures they appear, may have once contained multitudes of calcareous microscopic organisms, some of which have been removed *after* the consolidation of the strata, leaving either hollow casts, or having had the cavities subsequently filled with silica."

and exploring on shore we trawled in 300 fathoms, and among other things a fine specimen of the Pearly Nautilus (*Nautilus*), which we kept living in a tub for some time in order to observe its movements and attitudes.

On the 25th of July, we arrived at Kandavu, on the 28th we left for Suva, and on the 3rd of August we returned to Kandavu, remaining until the 10th.

The civilian staff were occupied in examining the reefs and observing the natural history of the islands; and in this we received friendly assistance from H.M. Consul Mr. Layard and from the Minister of King Cacobau. During our stay, a mixed party of naval and civilian officers went in the ship's barge to Mbaw and Ngau.

Between New Zealand and the Fiji group only two soundings were made at a greater depth than 1000 fathoms. Of these, one, at a depth of 2900 fms off Cape Turnagain, New Zealand, gave a bottom of "red clay" and a bottom-temperature of  $2^{\circ}$  C.; and the second, at 2900 fms,  $5^{\circ} 5' S.$ , long.  $172^{\circ} 56' W.$ , midway between the Kermadec and Friendly Islands, gave "red clay" and a temperature of  $2^{\circ}$  C. Serial temperature-soundings were taken; and the distribution of temperature was found to correspond, in its main features, with that previously met with in oceans communicating freely with the Pacific.

with clubs, spears, and bows with sheaves of poisoned arrows) were sufficiently friendly, nearly all the officers landed and spent a few hours rambling about the shore. It was not thought prudent to go far into the forest, which was very dense and luxuriant and came close down to the beach.

The natives were almost entirely naked, and certainly bore a very savage and forbidding aspect. One of them was manifestly greatly superior to the others, and appeared to exercise a considerable influence over them. He wore trousers and a shirt and a felt hat, and could speak English fairly. He recognized me, at once, as having seen me at the sugar-plantation in Queensland, where he had been for the usual three-years' engagement, and showed me, with great pride, a note from his former employer, saying that the bearer was anxious to return to his service, and that he would willingly pay his passage-money and all expenses, in case of his being given a passage to Brisbane. I had been paying some attention to the South-Sea labour question, and had formed a very strong opinion of the value to the inhabitants of these islands of the opportunity given them, by this demand for labour, of testing their capacity to enter into and mix with the general current of working men, and thereby possibly avoid extermination; and I was greatly pleased to see the result in this instance.

From the island of Api we shaped our course to the north-westward towards Raine Island, in a breach of the great barrier reef not far from the entrance of Torres Strait. On the 19th of August we sounded, lat.  $16^{\circ} 47' S.$ , long.  $165^{\circ} 20' E.$ , at a depth of 2650 fathoms, with a bottom of "red clay" and a bottom-temperature of  $1^{\circ} 7 C.$  ( $35^{\circ} F.$ ). A serial temperature-sounding was taken to the depth of 1500 fathoms; and it was found that the minimum temperature ( $1^{\circ} 7 C.$ ) was reached at a depth of 1300 fathoms, and that consequently a stratum of water at that uniform temperature extended from that depth to the bottom.

Serial temperature-soundings were taken on the 21st, the 24th, the 25th, the 27th, and the 28th of August in 2325, 2450, 2440, 2275, and 1700 fathoms respectively; and in each case the minimum temperature of  $1^{\circ} 7 C.$  (or a temperature so near it as to leave the difference within the limit of instrumental or personal error of observation) extended in a uniform layer, averaging 7000 feet in thickness, from the depth of 1300 fathoms to the bottom.

It will be seen by reference to the chart that on our course from Api to Raine Island we traversed for a distance of 1400 miles a sea included within a broken barrier, consisting of the continent of Australia to the west, the Louisiade archipelago, the Solomon Islands, and a small part of New Guinea to the north, the New Hebrides to the east, and New Caledonia and the line of shoals and reefs which connect that island with Australia to the south. The obvious explanation of this peculiar distribution of temperatures within this area, which we have called, for

reference, the "Melanesian Sea," is that there is no free communication between this sea and the outer ocean to a greater depth than 1000 fathoms, the encircling barrier being complete up to that

The "Melanesian Sea" is in the belt of the S.E. trade-winds, and the existence of a drift-current which traverses its long axis, at an average of half a knot an hour, is to the westward; evaporation is, consequently, throughout the course of the trade-winds, greatly in excess of precipitation, so that a large amount of the surface-water is continually being lost, and must, of course, be replaced, and it is so by an indraught of water from the outer ocean over the lowest part of the barrier, at the proper temperature and depth. We had previously found a temperature of  $12.7^{\circ}$  C. at 1000 fathoms on the 16th, the 19th, and the 21st of June 1873, off Australia and New Zealand, on the 17th of July in lat.  $25^{\circ} 5'$  S. and  $156^{\circ} 56'$  W., and earlier on the 10th of March in lat.  $47^{\circ} 25'$  S. Within the Melanesian Sea may be described generally as containing a small but varying proportion of the shells of Foraminifera, but more usually much broken up and decomposed. In some soundings the tube showed curiously interstratified deposits, being markedly in colour and in composition. The trawl was used on the 25th of August to a depth of 2440 fathoms. The shells were few in number—some spicules of *Hyalonema*, a

Animal life was not abundant. Many of the animals seemed dwarfed, and the fauna had somewhat the character of that of a harbour or estuary. The specific gravity of the surface-water was unusually low, falling on the 23rd, off Dobbo Harbour, to 1.02505, the temperature reduced to 15°·5 C., distilled water at 4° C. = 1.

After spending a few days shooting Paradise-birds and getting an idea of the natural history of the island of Wokaw, we left Dobbo on the 23rd and proceeded to Ké Doulan, the principal village in the Ké group. We then went on to the island of Banda, where we remained a couple of days, and thence to Amboina, which we reached on the 4th of October.

On the 26th of September, after leaving the Ké Islands, we sounded and trawled in 129 fathoms. The trawl brought up a wonderful assemblage of things, including, with a large number of Mollusca, Crustacea, and Echinoderms of more ordinary forms, several fine examples of undescribed hexactinellid sponges, and several very perfect specimens of two new species of *Pentacrinus*. Temperature-soundings were taken on the 26th of September and on the 3rd of October, at depths of 2800 and 1420 fathoms respectively; and on both occasions the minimum temperature (3° C.) was reached at a depth of 900 fathoms, indicating that the lowest part of a barrier inclosing the Banda Sea, bounded by Taliabo, Buru, and Ceram on the north, the Aru Islands on the east, Timor and the Salwatty Islands on the south, and Celebes and the shoals of the Flores Sea on the west, is 900 fathoms beneath the surface.

From Amboina we went to Ternate, and thence across the Molucca passage into the Celebes Sea, by the passage between Bejaren Island and the north-east point of Celebes. On the 13th, we trawled and took serial temperatures near Great Tawallie Island. The trawl brought up several specimens of a very elegant stalked halichondroid sponge new to science, and the thermometer gave temperatures sinking normally to a bottom-temperature of 2°·04 C. On the following day we sounded in 1200 fathoms, with again a normal bottom-temperature of 1°·9 C. It seems, therefore, that the Molucca passage communicates freely with the outer ocean; it does so at all events to the depth of 1200 fathoms, and most probably to the bottom, if it include greater depths.

In the Celebes Sea we had two deep soundings—on the 20th, to 2150 fathoms, and on the 22nd, to 2600 fathoms. On both occasions serial temperature-soundings were taken, and on both the minimum temperature of 3°·7 C. (38°·7 F.) was reached at 700 fathoms. A passage of this depth into the Celebes Sea is therefore indicated, very probably from the Molucca passage. This temperature corresponds almost exactly with that taken by Captain Chimmo in the same area. We trawled on the 20th; and although the number of specimens procured was not large, they were sufficient to give evidence of the presence of the usual deep-sea fauna.

Amboanga on the 23rd, and on the 26th we passed into  
trawled at a depth of 102 fathoms. On the 27th we  
fathoms, and took a serial temperature-sounding. A  
ature of  $10^{\circ}$  C. was found at 400 fathoms; so that the  
o regarded as the fourth of this singular succession of  
barriers of varying height from communication with  
observation in the main confirmed those of Captain  
ame locality. The minimum temperature reached was  
but we appear to have found it at a somewhat higher

and which here develops minute mutable pseudopodia, which are being constantly projected and withdrawn. Indeed the vibratile cilia appear to be but a modification of these pseudopodial processes of protoplasm.

Interposed between the endoderm and the ectoderm is the *fibrillated layer*. It is extremely well developed, and consists of longitudinal muscular fibrillæ, closely adherent to the outer surface of a structureless hyaline membrane—the “*Stützlamelle*” of Reichert. The fibrillated layer, with its supporting membrane, is so strong as to remain entire in a section of the animal after the tissues on both sides of it have been broken down.

The *ectoderm* is composed of two zones, a superficial and a deep. The superficial zone consists mainly of two or three layers of small round cells containing yellowish granules. Among these cells the thread-cells may be seen, lying chiefly near the outer surface of the body. Two forms of thread-cells may be here distinguished—one ovate, with the invaginated tube occupying the axis; the other fusiform, with the invaginated tube oblique.

The deeper zone of the ectoderm consists of a very remarkable tissue, composed of peculiar membraneless cells, each of which is prolonged into a tail-like process, so that the cells assume a claviform shape. In most situations, where this tissue is developed, the processes from several such cells unite with one another, so as to form branching, somewhat botrylliform groups, whose common stalk can be followed into the fibrillated layer. The author is thus enabled so far to confirm the observations of Kleinenberg on cells of apparently the same significance in *Hydra*. In *Myriothela*, however, these cells do not, as in *Hydra*, reach the surface. With the exception, apparently, of their condition in the transitory arms of the *Actinula* or locomotive embryo, they form everywhere a deep zone interposed between the muscular layer and the superficial layer of the ectoderm. This zone is designated by the author as the zone of *claviform tissue*. Though it is in intimate association with the fibrillated layer, the author did not succeed in tracing a direct continuity of the individual fibrillæ with the processes of the cells, as described by Kleinenberg in *Hydra*.

The author adopts, as a probable hypothesis, the views of Kleinenberg respecting the caudate cells of *Hydra*, which he regards as representing a nervous system. While the deep layer of ectodermal cells in *Myriothela* would thus constitute a nervous layer, the superficial layer would represent an epidermis; and since recent researches justify us in regarding the ectoderm and endoderm of the Cœlenterata as respectively representing in a permanent condition the upper and lower leaf of the blastoderm in the development of the higher animals, we should thus find *Myriothela* offering no exception to the general law, which derives both epidermic and nervous tissues from the upper leaf of the blastoderm.

The structure of the tentacles is in the highest degree interesting. In

ink-like portion, the condition of the endoderm departs from that of this tissue in the tentacles of other marine hydroids; there is no trace of the septate disposition so well marked in these. The tissue is, on the contrary, composed of a layer of small cells loaded with granules, and surrounding a continuous wide axile cavity.

At the base, in the terminal capitulum of the tentacle that the structure of these organs departs most widely from any thing that has been observed in the tentacles of other hydroids. Here a very distinct layer is developed between the muscular layer and the proper endoderm, which takes the place of the zone of claviform tissue. It is a hemispherical cap over the muscular lamella and endoderm, and is composed of closely applied exceedingly slender rod-like structures, their inner ends resting on the muscular lamella, to which they are perpendicular, the whole structure forcibly suggesting the structure associated with special sense-apparatus in higher animals. It is, however, but a modification of the tissue which elsewhere forms the claviform tissue.

In a radiating direction from the convex surface of this rod-like structure towards the external surface of the tentacle, may be seen numerous fine filaments, each of which, making its way among the cells of the endoderm, terminates distally in a very delicate transparent structure which carries, near its distal end, a minute styli-form

In the female, the primitive plasma becomes gradually differentiated into a multitude of cell-like bodies having all the characters of true ova with their germinal vesicle and spot. They are entirely destitute of enveloping membrane.

These bodies next begin to coalesce with one another into numerous roundish masses of protoplasm, which develop over their surface minute pseudopodial retractile processes.

The masses thus formed still further coalesce with one another; and there results a single spheroidal plasma mass, through which are dispersed numerous small spherical vesicles, mostly provided with a nucleus. These vesicles appear to be nothing more than the nucleolated nuclei of the coalesced ovum-like cells.

About the time of the completion of this last coalescence, the resulting plasma mass, enveloped in an external, very delicate, structureless membrane, is expelled, by the contraction of the sporosac, through an aperture formed by rupture in its summit.

Immediately after its expulsion, it is seized, in a manner which forcibly suggests the supposed action of the Fallopian tube on the mammalian ovum at the moment of its escape from the Graaffian follicle, by the sucker-like extremities of certain remarkable bodies, to which the author gave the name of *claspers*, which are developed among the blastostyles, and resemble long filiform and very contractile tentacles.

It is apparently now that fecundation is effected; for the plasma becomes again resolved into a multitude of roundish masses. This phenomenon may be regarded as representing the yelk-cleavage of an ordinary ovum. Reasons are assigned for believing that it is through the agency of the claspers that fecundation takes place; and the claspers are compared to the hectocotylus of Cephalopods, and to certain organs by which fecundation is effected among the Algæ.

The mulberry-like mass thus formed, surrounded by its structureless membrane, which has now acquired considerable thickness and forms a firm capsule, continues to be held in the grasp of the claspers during certain subsequent stages of its development. An endoderm and ectoderm with a true multicellular structure become differentiated, a central cavity is formed by excavation, and the germ becomes thus converted into a spheroidal non-ciliated *Planula*. This, after acquiring certain external appendages, ultimately escapes, by the rupture of the capsule, as a free actinuloid embryo.

The actinuloid, on its escape from its capsule, is provided not only with the long arms already noticed by Cocks and Alder, but with short scattered clavate tentacles. The short clavate tentacles become the permanent tentacles of the fully developed hydroid; the long arms, on the other hand, are purely embryonic and transitory.

The long embryonic arms originate in the spheroidal *Planula*. They are formed by a true invagination, and at first grow inwards into the

Particulars of the Transit of Venus across the Sun,  
9, 1874, observed on the Himalaya Mountains,  
e, at May-Villa Station, Lat.  $30^{\circ} 28' N.$ , Long.  
Height above Sea 6765 feet."—Note No. I. By  
HENNESSEY, F.R.A.S. Communicated by Prof.  
O.C.L., Sec. R.S. Received January 2, 1875.

May Villa, 9th December, 1874.

ring in the great interest excited by the transit of Venus,  
this forenoon, I proposed that I should observe the event  
real of the Royal Society, which Capt. J. Herschel, R.E.,  
om India, had temporarily placed at my disposal : and the

or with a spectroscope mounting a single simple prism. The polar axis may be shifted for latitude. The equatoreal was set up and adjusted in an observatory-tent, of which the canvas top was removed during observation.

I found from actual trial that the most suitable eyepiece for both ingress (sun's altitude  $2^{\circ} 24'$  to  $7^{\circ} 29'$ ) and egress (sun's altitude about  $26^{\circ}$ ) was that of 125 power; accordingly *this* eyepiece alone was employed at the contacts. It was, however, impossible to adopt the same dark glass for both the higher and lower altitudes, without sacrificing definition on one of the two occasions. Accordingly I selected for ingress two glasses which, combined, gave a neutral or bluish field; and for egress I changed one of these for a deep-red glass, so that the field now presented a moderately deep red. The glasses were quite flat, and lay against one another in intimate contact, giving excellent definition. I may here add that, thanks to Manrakan, artificer, G. T. Survey, the clock behaved with perfect regularity; nor was there the smallest instrumental disappointment throughout the work. As regards procedure during transit, my friend Mr. W. H. Cole, M.A., counted seconds audibly from the journeyman chronometer placed before him; while Baboo Cally Mohun Ghose, computer, took up a position by my side, noting down such remarks as the phenomena, viewed through the equatoreal, elicited from me. Nor, as we stood informed, were the events to be recorded few in number. At, for instance, ingress, internal contact, the light between the cusps was to vary suddenly; the cusps were to meet. Then came "the pear-drop," "the ligament;" what should be its length, what its breadth in terms of Venus's diameter, what its shape? when would it break? and, lastly, which of the known descriptions would it resemble? Primed on these points, we settled on a programme which should include them all, and time after time we went through the necessary rehearsals for perfecting ourselves in our parts. So much for what we had to expect, and now for a few words on the weather.

I moved up to my mountain-station on the afternoon of December 1. The day following I was busy fixing my station, adjusting instruments, &c. Up to this the sky had been sufficiently clear; but from the 3rd there set in an alternation of weather, which, without running into extremes, kept me in a state of miserable suspense, to say nothing of the additional watching and toil in observing for time. This state of affairs appeared drawing to a climax, when the 8th December arrived, and the clouds looked blacker, while the mist, which generally precedes snowfalls here, began as usual to settle down on the internal and still more lofty ranges of hills. About 2 P.M. on this day there were a few drops of rain or sleet, so few that they might almost have been counted; and later on, as the sun began to set, the heavy cumuli evolved themselves into strati, which, spreading their even canopy over us, left something like decimal 0 of sky visible; and this at 10 o'clock at night! At 4 next morning, Dec. 9,

ted on, the sky was without speck or cloud; the air was so brilliantly clear, that even the most exacting of observers could not have desired more favourable circumstances for view-  
ing the transit. In brief, I enjoyed most exquisitely clear weather  
conditions—such weather as occurs not frequently even at

to describe the phenomena of the transit. In doing so  
I mean to speak of Venus as she appeared *across* the sun's  
portion of her own limb is seen against the sun, and the  
rest against the sky. The former portion I shall call Venus's  
limb, or  $V_1$ . Again, I shall require  
a ring of light around  $V_1$ , which I shall indicate by  $L_1$ , the  
ring around  $V_2$  being understood by  $L_2$ . Another point is  
that who has watched, say the sun's limb, especially at a low  
power, must be aware of the turmoil or ebullition  
which appears, very much as if the limb was being boiled. I shall  
indicate this turmoil by "boiling."

With the telescope well and carefully adjusted for focus, I  
saw the coming first external contact, but to no purpose; for I  
did not see Venus's limb until after it had made an indentation on the  
sun's limb, the latter boiled sensibly, but by no means violently. It  
seemed as if with minute spikes projecting inwards, all of

diffused light; and at first I estimated this annulus at 3" in breadth. It was probably brightest about the point where the chord above named cut

Ingress.

The annular ring of light could be distinguished, in continuation, around the limb on the sun; but as this continuation was rendered visible chiefly by the movements taking place in it, it is necessarily absent here.

$V_k$ . At 6<sup>m</sup> before first internal contact, I estimated  $L_k$  at 4" in breadth; at the same time my notes contain the remark, "definition excellent." At 3<sup>m</sup> 24" before first internal contact I remarked, "light-ring quite distinct;" and 1<sup>m</sup> 16" later I stated, "light-ring quite bright." Indeed the annulus  $L_k$  was so plain that, after recording the time of transit for the dark edge  $V_k$ , I even made a conjectural record as to the time when the bright edge ( $L_k$ ) transited across the sun's limb. Of course this latter estimate was based on *recollection* of the width of  $L_k$ , and not on any visible fact; for as  $L_k$  came on the sun's disk, the lesser light of the former merged into the greater light of the latter. On the whole, I am of opinion that  $L_k$  was between 2" and less than 4" in breadth.

*Ingress* (continued).—"And now for 'the pear-drop,' 'the ligament,' &c.," I mentally exclaimed, as I watched the following limb of Venus which had just transited. From what has been stated it will be seen that as  $V_k$  passed onwards from the sun's limb, it was followed immediately and visibly by the light-ring  $L_k$ ; so that, unless Venus *suddenly shot backwards across this ring of light*, there could be no "pear-drop" and no "ligament." Fully expecting this retrogression, I still watched intently for the event, while my friend Mr. Cole went on deliberately enumerating seconds amid the complete silence enforced on all others around;

present than the stump of a broken blacklead pencil and a blue-red carpenter's pencil. A better sketch will be forwarded hereafter. [A woodcut of the better sketch will accompany Note No. 2.—G. G. S.]

*the Transit of Venus across the Sun.* [Feb. 11,

any such event in vain. Venus glided resolutely on—  
break of *light* she was leaving behind grew wider and still  
t, when a belt of light representing 10 or 15 minutes lay  
the sun's limb, I exclaimed (and I believe much to the  
all concerned), "*there is no pear-drop and no ligament.*"  
us for some half an hour after this, and then turned to

—The substitution of spectroscope for eyepiece cannot  
s instrument without a considerable amount of adjust-  
s had been performed, and we had taken a hasty break-  
the slit across the *centre* of Venus's disk, and found that  
nd all along the length of the bright solar spectrum,  
turned to us reflected no light. I next placed the slit  
us's disk. This gave a faint glimmer of narrow light in  
band, i. e. this glimmer was slightly brighter than the  
which it appeared. I looked intently for Venus's air-  
as the feeble dispersion of the prism would show, the  
the glimmer from Venus's edge were identical in all  
solar lines. I repeated these experiments as long as  
and then, with artificer Manrakan's help, reverted  
s for mounting the eye-end and eyepiece employed at  
lv stated, it was now necessary to substitute a dark-

(1) In view of the light-ring  $L_n$ , and of the peculiar boiling annulus around  $V_n$ , which may be called  $L_n$ , I have no doubt that  $L_n$  was, in fact, a continuation of the light-ring  $L_n$ , which latter, beyond all question, was plainly visible; and under these circumstances it may be urged that Venus is surrounded by an atmosphere which at the time was made visible to the extent of 2" to under 4" in breadth.

(2) As a matter of fact, the pear-drop and the ligament were visible at a height of 2200 feet, but at 6500 feet the ligament was invisible. The influence generally of height of station, from this evidence, appears undeniable; but the phenomenon still remains to be accounted for definitely. If, however, an effective atmosphere of  $x$  breadth around Venus be conceded, this atmosphere may be supposed to stop a certain amount of direct light from the sun, producing a slight shade around Venus corresponding to the breadth  $x$ . This shade would, I conceive, be quite invisible when its outer edge is backed by the sun's bright light; but could we contract the sun to a diameter equal to that of Venus plus twice  $x$ , and make Venus and the sun concentric, it appears likely that we should see a shaded annulus right round Venus between her limb and that of the sun; further, that the annulus would appear darker at low than at higher altitudes, and would become invisible when the observer was raised above a sufficiency of the earth's atmosphere. Should these suggestions prove tenable, the ligament seen would break when the outer edge of the shade, corresponding to  $x$ , transited across the sun's limb.

(3) Solar light shining through Venus's atmosphere, if any, produces no alteration in the lines of the solar spectrum, so far as the dispersion of a single simple prism can show. Also Venus's face, turned towards us, reflects no light during transit, subject to the same instrumental test.

Night of 10th Dec., 1874.

III. "Appendix to Note, dated November 1873, on White Lines in the Solar Spectrum." By J. B. N. HENNESSEY, F.R.A.S. Communicated by Professor STOKES, Sec.R.S. Received January 11, 1875.

After detection of the white lines 1650 and 1658 (Kirchhoff's scale) at Mussoorie in November 1873, I discovered two other such lines before leaving that station of observation, viz. 2009 and 2068 (about). On 20th November, 1873, I packed up the spectroscope, taking particular care that the prisms should not shift from the position they then occupied.

On 28th November, 1873, I set up the spectroscope in the Dome Observatory at Dehra, in the valley below, the prisms retaining their former position, and my recollection of the white lines seen at Mussoorie

*on the Number of Figures in Primes.* [Feb. 18,

II. "On the Nature and Physiological Action of the *Crotalus*-poison as compared with that of *Naja tripudians* and other Indian Venomous Snakes; also Investigations into the Nature of the Influence of *Naja*- and *Crotalus*-poison on Ciliary and Amoeboid Action and on *Vallisneria*, and on the Influence of Inspiration of pure Oxygen on Poisoned Animals." By T. LAUDER BRUNTON, M.D., F.R.S., Sc.D., M.R.C.P., and J. FAYER, C.S.I., M.D., F.R.C.P. Lond., F.R.S.E., President of the Medical Board at the India Office. Received January 7, 1875.

In our former papers we described the general phenomena accompanying the physiological action of cobra- and *Daboia*-poisons on warm-blooded animals, reptiles, fishes, and invertebrata. We propose in this

*Brunton and Fayrer on the Physiological* [Feb. 18,

with these the action of the *Crotalus*-virus in its general effects on the functions, organs, and tissues, and especially as it acts on the blood and vessels as regards a marked influence in causing general and local extravasations of blood generally and locally; and, finally, the action of snake-poison generally on ciliary and contractile elements—or that which represents its action on contractile elements—that which is caused through the medium of the nerve-distribution.

That there is little difference between the physiological action of the crotaline or viperine and the colubrine virus. The mode of action brought about is essentially the same in all; though there are, even when allowing for individual peculiarities, that are marked by some points of difference sufficiently characteristic to be noted in detail.

They have already expressed our belief that death is caused by the action of the *Hydrophis*-poison, 1st, through its action on the nerve-centres, especially on the medulla, inducing paralysis; or 2nd, in some cases (where the poison has entered the system in large quantities and has been conveyed more directly to the heart) tetanically in systole, of cardiac action, probably owing to its action on the cardiac ganglia; 3rd, by a combination of the two; or 4th, by a septic condition of a secondary nature, and

Hæmorrhages or hæmorrhagic extravasations and effusions, both local and general, occur in all varieties of snake-poisoning.

But we observe (and in this our observations are in accord with those of Weir Mitchell) that there is a greater tendency to both local and general hæmorrhage and extravasation of blood and of the colouring-matter of the blood, especially as observed in the peritoneum, intestines, and mesentery, and also probably to a more direct action on the cord (*vide* Experiments I., III., V., VI., VII., IX., XI., XIV., XV.), than in poisoning by either cobra or viper (*vide* Experiments IV., VII., XIII., XVI., XVII., XX.).

The viscera and other tissues, after death, are found congested and ecchymosed, and in some cases to a great extent, seeming to show that either a preternatural fluidity of blood or some important change in the vessels, favouring its exudation, has occurred.

But with regard to the blood itself we have observed that it does form a coagulum after death, generally, if not invariably; as we have noted to be the case, though not to the same extent, in the blood of animals that have succumbed to the *Daboia*-virus\*.

With reference to the coagulation or non-coagulation of the blood in cases of snake-poisoning, we observe that the following conclusions have been arrived at by Mr. Richards and the Calcutta Committee (*vide* p. 45 of their Report).

"We now propose to deal with the physical changes produced by snake-poisoning on the blood. From observations which have been made by Mr. Richards and ourselves, we have arrived at the following conclusions.

"*The blood appears to remain fluid after death under the circumstances noted below :—*

"1st. When a large quantity of the cobra-poison has been directly injected into the circulation, as, for example, into an artery or a vein†.

"2nd. In cases where animals or men have been poisoned by the bite of vipers, such as the Russell's viper.

"3rd. In all cases of snake-bite, whether from the poisonous colubrine or viperine genera, in the human subject‡.

"*The blood undergoes either partial or complete coagulation under the following conditions :—*

"1st. When a small quantity only of the cobra-poison has been injected into a vein or an artery.

"2nd. In cases where the lower animals have been bitten by the cobra.

"Why the admixture of a large and quickly fatal injection of the cobra-virus into the circulation of animals should produce comparatively

\* In Dr. Fayer's Indian experiments the blood of animals dead from *Daboia*-poison nearly always remained fluid after death.

† This is not always so.—J. Fayer.

‡ Not always so.—J. Fayer.

*Brunton and Fayrer on the Physiological* [Feb. 18,

ility of the blood or interfere with its ordinary coagulability  
oval from the body or after death, and why the injection  
d more slowly fatal quantity should interpose no obstacle  
agulation, are questions extremely difficult to account for  
e can only state the fact that, in the one case, coagulation  
, and in the other this coagulation is retarded or altogether  
ome cause at present unknown."

g experiments were made on the physiological action of the

was good enough to send about six grains of the dried  
lus—the species not named, but it is believed to be of  
us.

ison supplied is said to be about 6½ years old, and was  
r August at the natural temperature, and has since then  
l in a phial. It was tried by Dr. Mitchell and found  
ars ago.

appearance of fractured fragments of dried gum-arabic,  
arker yellow colour, but otherwise resembling the dried  
t from Bengal.

12.20. Twitchings much increased, now mainly in head and neck, not so much in hind legs.

12.28. Guinea-pig quiet, but with occasional twitchings; sluggish and disinclined to move.

1.30. Sluggish in moving; can still move about, though disinclined to do so. The punctured thigh is very blue.

The rest of the notes of this experiment were lost.

The animal died.

### Experiment III.

June 10th, 1874.— $\frac{1}{4}$  of a grain of *Crotalus*- and  $\frac{1}{4}$  of a grain of cobra-poison were carefully weighed and diluted, each with ten drops of distilled water. Two full-grown guinea-pigs of equal weight were then selected.

The solution of *Crotalus*-poison was injected into the peritoneal cavity of guinea-pig No. 1 at 1.52 P.M.

1.55. Muscular twitchings of head and neck.

2 P.M. Startings and twitchings continue.

It gives faint squeaks occasionally, as though the sudden startings which occur at intervals of 5 or 6 seconds cause pain.

2.5. Twitchings continue.

2.8. Very restless; twitchings going on, but no paralysis yet.

2.17. The same.

2.25. Restless and weaker; but still moves freely on being roused.

2.42. Sluggish; drags the hind legs.

2.58. Weaker; rolls partially over on one side, but can run when roused.

3.3. Lying on side, but can be roused; is partially paralyzed in hind legs. Respiration abdominal and hurried.

3.5. Nearly quite paralyzed; is roused with difficulty.

3.7. Can still be roused. Abdomen distended and painful; cries out when it is touched, as though peritonitis were setting in.

3.12. Can be roused with difficulty; respiration hurried; convulsive movements of fore legs and neck. Can still stagger for a few paces; but coordination of muscular power much diminished.

3.30. In violent convulsions.

3.38. Convulsions continue.

3.45. Quiet. Paralyzed; but reflex action still continues.

3.55. Dead in 2 hours and 3 minutes.

3.56. Electrodes in cord cause twitching of muscles of the back, and very slightly in those of the legs: the cord was evidently all but paralyzed. Muscular fibre contracts freely to direct stimulus of current. The intestines were ecchymosed and congested. There were effusions of red serum into the peritoneal cavity, and much ecchymosis of peritoneum and subperitoneal and intra-muscular areolar tissue. Peristaltic action continued faintly.

*Brunton and Fayrer on the Physiological* [Feb. 18,

heart has ceased to contract 4 minutes after apparent death ;

their bright pink.

these two cases, except in the energy with which the cobra exceeded the *Crotalus*.

*Crotalus.*

Twitchings; restless; squeaks; sluggish; ataxy; paralysis. Hurried respiration. Peritonitis. Convulsions. Death in 2 hours 3 minutes. Coagulated blood. Ecchymosis and extravasation of serous effusion well marked. Cord paralyzed. Muscles retain irritability.

*Cobra.*

Twitchings; excitement; squeaks; sluggish; ataxy; weakness; paralysis. Convulsions. Death in 20 minutes. Spinal cord and nerves paralyzed. Muscles irritable. Heart distended. Blood congested. Ecchymosis. Congestion less than in *Crotalus*.

*Experiment V.*

June 10th.—A grain of *Crotalus*-poison diluted with water was injected into the peritoneum of a full-grown guineapig at 2.40 P.M. Twitchings began almost immediately.

3.3. Restless; startings; staggers on hind legs.

3.20. Very weak, especially in hind quarters. General paralysis setting in. Abdomen distended and very tender.

3.30. In convulsions. Still feels when the abdomen is touched.

3.37. Paralyzed; but feels the touch. Reflex well marked.

3.45. Apparently dead in 65 minutes.

3.48. Cavities opened. Auricles flickering. Blood from heart and great vessels coagulated firmly. Abdominal cavity and areolar tissue and subperitoneal tissue infiltrated with bloody serum. Much ecchymosis of peritoneum and intestines, but not of lungs. Cord and nerves paralyzed. Muscles contract vigorously to induced current.

*Action of Crotalus-poison on Rabbit.**Experiment VI.*

$\frac{1}{4}$  of a grain (.015 gramme) of the same *Crotalus*-poison, dissolved in 1 cub. centim. of water.

The jugular vein of a large white rabbit was exposed, and the above solution was injected into it at 1.50 P.M.

At 1.51 violent convulsions, with opisthotonos.

At 1.53 apparently quite dead. Artificial respiration commenced immediately. Heart acting still, though feebly and with irregular flickering contractions. Spinal cord exposed. Electrodes applied; no reaction.

2.12. Heart still contracting feebly.

2.15. Faint contractions of heart still observable. Ventricles punctured, and blood withdrawn. Peristaltic action has ceased.

2.20. Feeble cardiac movements continue.

2.21. Heart has now ceased. Muscles react to direct current. Death

*Brunton and Fayrer on the Physiological* [Feb. 18,

paralysis of medulla and cord. The blood taken from great vessels did not coagulate. At 4 P.M. it was still very florid in colour.

Under the microscope nearly 2 hours after apparent death, puscles appeared natural; the red corpuscles not in very much crenated, though a few retained their natural

as natural to test-paper.

#### *Experiment VII.*

$\frac{1}{4}$  of a grain ( $\cdot 015$  gramme) of dried cobra-poison, dissolved in . of water, was injected into the jugular vein of a large of the same size as in the previous experiment, at 2.55 P.M. passed at once into violent convulsions, and was apparently could be removed from the board, within one minute. The immediately exposed, artificial respiration having also been electrodes applied, with strong current; no reaction; the cord paralyzed.

ained at 2.59. Heart had ceased to contract. Ventricles ntracted. Auricles distended with blood. Phrenic irri- ralyzed. Diaphragm, when directly irritated by current, faintly, whilst the neighbouring muscles contract vigorously. action goes on. Electrodes applied to vagus appear to

circulation have the power in some cases of annihilating almost instantaneously the irritability of the cord and medulla, as in others they have of arresting the heart's action.

#### *Experiment VIII.*

*June 17th.*—Ten drops of the blood of the rabbit described in the last experiment, poisoned by *Crotalus*-virus, were injected into a guineapig's thigh at 3.40 p.m.

The guineapig was not apparently affected constitutionally by the poisoned blood. It was alive the next morning; but the leg was swollen and discoloured. It ultimately recovered.

#### *Experiment IX.*

*June 24th, 1874.*—A full-grown cat was chloralized at 1.20 p.m.  $\frac{1}{4}$  of a grain of *Crotalus*-poison, diluted with 1 cub. centim. of water, was injected into the jugular vein. The respirations were immediately quickened.

1.21. Twitching of muscles generally.

1.22. Efforts to vomit. Forcible extension of limbs.

1.24. Hurried respiration and retching. Reflex action perfect.

1.30. Muscular twitching and tetanic stretching of limbs. Efforts to vomit continue. Micturition. Rolls over on the ground.

1.34. Ataxy. Staggers when walking, which it can only do for a few paces. Peculiar twitching of diaphragm; not synchronous with respiratory movements. Rolls over on its side.

2 p.m. In the same state.

2.8. Injected  $\frac{1}{8}$  of a grain more of the poison into the same jugular vein. The animal immediately got up and walked, comparatively steadily, for several paces, as though it had been stimulated, and then rolled over.

2.16. Twitching of diaphragm continues at the rate of 150 per minute.

2.18. Again got up and walked for a few paces; but it is gradually becoming more paralyzed.

2.44. Violent tetanic spasms of limbs. Reflex action diminished.

2.46. Reflex action gone from eyes. Deep sighing respiration.

2.47. Convulsions. Death. Body opened immediately. Lungs deeply congested and much ecchymosed. Deep red gelatinous effusion all about the roots of the lungs. Heart contracting. Electrodes applied to phrenic caused vigorous contraction of diaphragm.

2.50. Heart ceased to contract 3 minutes after respiration had ceased.

2.52. Electrodes in cord; do not cause contraction of limbs.

2.54. The sciatic nerve, when irritated, conveys impressions; muscles of legs contract. Blood from the heart and great vessels did not form a coagulum, and remained permanently fluid. Red corpuscles of blood were much crenated.

Death in this case appeared to be caused through the medulla.

Brunton and Fayrer on the Physiological [Feb. 18,

*Experiment X.*

74.—Action of *Crotalus*-poison on the frog.

leg was ligatured excluding the sciatic nerve.

*Crotalus*-poison was injected into the lymph-sac at 12.32

h, but not otherwise affected.

same condition.

12.3, noon. Sluggish, but can still move.

Found dead this morning early; pupils contracted.

plied; no reaction in either cord or nerves on either side  
current.

have been dead some hours.

*Experiment XI.*

At 3 P.M. same day a solution of *Crotalus*-venom was  
e dorsal lymph-sac of a frog, the aorta having been pre-  
l, so as to prevent the poison from affecting the trunks  
extremities of the sciatic nerves.

og seems quite unaffected.

12.30, noon. Frog dead; not rigid; mouth open.

ard with strongest current does not cause contraction of

place, and to the naked eye the mesentery became discoloured by patches of ecchymosis in the course of the small blood-vessels, like the foliage on the branches of a tree.

There could be no doubt that the local action of the poison had a marked effect in producing extravasation of blood.

#### *Experiment XIII.*

A similar experiment was repeated on another part of the mesentery of the same cat with cobra-poison, exactly as the *Crotalus*-poison had been applied in the previous experiment. This was carefully watched, but no extravasation took place; there was a marked difference in the result of the application of the two poisons, at all events as far as these two experiments were concerned.

#### *Experiment XIV.*

*August 12th, 1874.*—A cat was chloralized at 2.30 p.m. Mesentery exposed and placed under microscope on warm stage.

*Crotalus*-poison applied to mesentery; circulation soon diminished in some vessels but continued vigorously in others. Isolated extravasated patches soon made their appearance of a triangular form, others followed and coalesced with these until a network was formed in the course of the vessels all over the field. The extravasation soon became general, the circulation still continuing slowly.

#### *Experiment XV.*

A fresh portion of mesentery of same cat exposed. Intestines becoming cold and circulation now very languid.

Cobra-poison applied.

No apparent effect produced; but the circulation is very languid, indeed has almost ceased, so that the results of this experiment are not conclusive.

#### *Experiment XIV.*

*August 14th, 1874.*—A cat was chloralized, part of mesentery withdrawn, and placed under microscope on warm stage.

Dried cobra-poison dissolved in a salt solution, .75 per cent., applied to the mesentery at 4.10 p.m.

4.14. Circulation is languid, almost ceased in some vessels.

4.18. Slight extravasation taking place where the poison has been in contact.

4.20. Extravasation rather more obvious.

4.35. Exposed another part of the mesentery; examined the state of the circulation before applying the poison. Blood flowing languidly.

Poison applied at 4.37; at first it seemed rather to accelerate the movement of the blood.

tion continues at same rate.

rate.

comes more languid.

tion has ceased, but yet there is no marked extravasation.

*Experiment XVII.*

tion of the same mesentery had cobra-poison applied, but  
our there was no sign of extravasation.

*Experiment XVIII.*

of mesentery exposed of same cat, and diluted *Crotalus*-  
at 4.52 P.M.

on was rather languid at the time, and apparently became

extravasation had taken place, the blood flowing very lan-

tion still going on, but very slowly; no extravasation; it  
ed.

*Experiment XIX.*

a fresh portion of the mesentery was exposed; to one  
to the other *Crotalus*-poison was applied, and the effect

with the object of testing the influence of snake-poison on ciliary action, especially in reference to its comparative action on vegetable protoplasm, as will be seen by his remarks.

*Experiment XXI.*

*Influence of Cobra-poison on Ciliary Action.*

*June 29th, 1874.*—Ciliated epithelium from the frog's mouth was treated with a solution of cobra-poison and examined under the microscope.

At 1.35 P.M., when examined, the action of the cilia was vigorous.

At 1.45 it was much diminished.

At 1.55 it had entirely ceased.

*Experiment XXII.*

Ciliated epithelium placed under microscope ; one part was treated with water, the other with the poisoned solution.

At 2.10 P.M. ciliary motion vigorous in both, perhaps more so in that subjected to the poisoned solution.

2.18. Non-poisoned cilia active. Poisoned cilia very feeble.

2.20. Non-poisoned cilia still active. Poisoned cilia very feeble.

2.24. Non-poisoned cilia active. Poisoned cilia very languid.

2.30. Non-poisoned cilia still active. Poisoned cilia have entirely ceased to act.

It is evident from this that the poison first stimulates and then destroys the activity of the ciliary action.

*Experiment XXIII.*

*August 14th.*—Frog's blood placed in salt solution, .75 per cent., at 1.25 P.M. on warm stage, and then subjected to the action of cobra-poison.

At first the amœboid movements of white corpuscles went on vigorously. At 2 P.M. they had ceased, or very nearly so, in all that appeared in the field.

2.30. All movement had entirely ceased. The red corpuscles seemed more flattened, the nucleus more visible, and the edges better defined, assuming a pointed and more oval form than usual.

*Experiment XXIV.*

*August 25th, 1874.*—Newts' blood examined under  $\frac{1}{8}$  object-glass on hot stage, white corpuscles moving slowly. Cobra-poison applied, but no perceptible change observed.

The following communications were received from Mr. C. Darwin on the action of some of the same cobra-poison on vegetable protoplasm :—

“You will perhaps like to hear how it acted on *Drosera*. I made a solution of  $\frac{1}{4}$  gr. to 3ij of water. A minute drop on a small pin's head

runton and Fayrer on the *Physiological* [Feb. 18,

on several glands, more powerfully than the fresh poison  
ing.

ed three leaves in 90 minims of the solution ; the ten-  
e inflated and the glands quite white, as if they had  
ing water. I felt sure that the leaves were killed ; but  
ersion they were placed in water, and after about 48  
, showing that they were by no means killed. The  
umstance is, that, after an immersion of 48 hours, the  
cells was in unusually active movement. Now, can you  
er this poison, if diluted, arrests the movement of

gr. [of cobra-poison] in 3j of water, so that I was able  
aves. It acted as before, but more energetically ; and  
early, this time, that the solution makes the secretion  
cloudy, which I have never before observed. But here  
able point ; after an immersion of 48 hours, the proto-  
cells incessantly changes form, and I never saw it on  
so active. Hence I cannot doubt that this poison is  
protoplasm ; and I shall be very curious to find out in  
er you have tried its action on the cilia and on the  
s of the blood. If the poison does arrest their move-  
lat there is a profound difference between the pro-

1.45. The muscle has lost its irritability; does not respond to the strongest current.

*Experiment XXVI.*

At the same time (1.25 P.M.) the gastrocnemius from the other leg of the same frog immersed in water. Did not immediately contract like that placed in the poisoned solution.

1.30. Contracts strongly to current at 15 c. m. of Du Bois Reymond's coil, more than the poisoned muscle at 11, at the same moment.

1.45. Contracts distinctly at 11, whilst the poisoned muscle has lost all irritability.

From this it is evident that the poison first stimulates the muscular fibre to contract, but rapidly afterwards destroys its irritability.

*Experiment XXVII.*

The gastrocnemii of a frog were again treated in the same way as in the previous experiment, with precisely the same results.

*June 28th.*—Made several experiments with cobra-poison on ciliated epithelium of frog's mouth, and found that it at first accelerated, then destroyed, the action of the cilia.

*Experiment XXVIII.*

*To test the effects of Cobra-poison, when swallowed, on the Frog.*

*June 24th, 1874.*—At 2.25 P.M. about  $\frac{1}{8}$  of a gr. of dried cobra-poison was passed down a frog's throat.

2.30. Frog making violent efforts to vomit. Gaping. Head thrown back tetanically.

2.34. Bloody mucus vomited with violent efforts \*.

2.50. Moves with difficulty; is becoming paralyzed. Efforts to vomit continue.

3. Much the same.

3.5. Very weak; still tries to vomit.

3.10. Reflex action still well-marked.

3.15. Motor nerves apparently quite paralyzed.

3.20. Apparent death.

*Artificial Respiration with pure Oxygen.*

As life had been prolonged for many hours in snake-poisoning by artificial respiration with atmospheric air, it was thought expedient to ascertain if the more complete oxygenation by the undiluted gas would be more efficacious, as it seemed might be possible; accordingly the following experiment was made on the 24th April, 1874.

\* This experiment is especially interesting, as showing that frogs do occasionally vomit, a fact which has been denied by some physiologists.

unton and Fayrer on the *Physiological* [Feb. 18,

*Experiment XXIX.*

dried cobra-poison dissolved in distilled water was  
injected with the hypodermic syringe.

poisoning were rapidly manifested. A tube had been  
inserted into the trachea, and respiration was commenced  
and was manifest.

oxygenation, with oxygen contained in a large bag, was steadily  
continued for several hours, but with no better effect than in other similar  
cases. Atmospheric air was used for the same purpose. At the  
end of several hours, apparent death had occurred; the heart con-  
tinued to beat about two minutes after the respiration ceased.

On the florid condition of the blood, there was no obvious  
difference between the effect of oxygen and that of common air. It did  
not appear that, as far as the effects produced by the poison were  
concerned, it differed in its action from common air.

*Experiment XXX.*

A little cobra-poison, dissolved in water, was added to  
some cells scraped from the mantle of a freshwater  
mollusk. There was a large ciliated cell, which, before the addi-  
tion of the poison, had been moving slowly, although its cilia were  
beating. Immediately after the addition of the poison the cell

*Experiment XXXIII.*

A little dilute cobra-poison was added to a piece of the mantle of a fresh-water mussel. The cilia began immediately to move much more rapidly. This was watched for some time. Ciliary motion not affected, or at all events not arrested, after more than half an hour.

*Experiment XXXIV.*

December 10th, 1874.—A piece of the gills of a freshwater mussel placed under the microscope and a little cobra-poison added at 10.40 P.M. The cilia were extremely active.

At 10.55 still active.

11.5. Several ciliated amœboid masses are now quiet instead of rolling over and over as they did, but the cilia on their surface are still moving.

11.15. The cilia on these Infusoria have now nearly all stopped. A few are moving slowly, whilst those on the gills are but little affected.

11.55. Cilia on the gills are still quite active. Those on the ciliated bodies still moving, rather more actively than before.

1.30. Cilia on gills have become much more sharply outlined. Many are standing still, though many still move briskly.

*Experiment XXXV.*

To another specimen a strong solution of cobra-poison was added at 10.50.

1.30. Cilia still moving.

*Experiment XXXVI.*

A third specimen was laid in an almost syrupy solution of dried cobra-poison at 11.28.

At 11.40 no effect observable.

1.30. Some have stopped, but numbers are still moving quite briskly.

In this case the poison seemed not to have any action on the ciliary motion.

*Experiment XXXVII.*

January 6th, 1875.—At 3.40 some diluted cobra-poison added to *Vallisneria*. Circulation going on vigorously. About  $\frac{1}{10}$  grain in three drops of water.

3.58. The movements are unchanged.

5 P.M. Movements going on as before.

*Experiment XXXVIII.*

Added some solution of cobra-poison at 4 P.M. to another specimen of *Vallisneria*.

4.10. No change.

4.45. Circulation goes on vigorously.

4.55. Perhaps rather less brisk in their movements.

*Letter from Mr. R. Mallet.*

[Feb. 25,

These experiments show that cobra-virus must be regarded, to a certain extent, as a poison to protoplasm, seeing that it arrested the movements in Infusoria\* (*vide* Experiments XXX., p. 100). Still it cannot be regarded certainly as a very powerful poison. The cilia of the freshwater mussel continued to move in a strong solution of cobra-poison; though in other cases the action was apparently arrested even in weaker solutions. In the case of cilia from the frog's mouth, the action was definite, but action was not invariably destroyed. The effect of the poison on the amoeboid movements of the cells was not very definite. In the case of *Vallinaria*, the cells went on with undiminished vigour after the addition of cobra-poison for two hours.

*February 25, 1875.*

MR. HOOKER, C.B., President, in the Chair.

Resolutions were laid on the table, and thanks ordered for

A communication from Mr. Robert Mallet, F.R.S., was

an important record for reference in the future progress of seismology, I have thought it desirable that it should be presented to the Royal Society, with a view to it being preserved in the Archives of the Society; and I would beg to be informed whether the Council may think fit to accept the deposit.

I remain, dear Sir,

Truly yours,

ROBERT MALLET.

The thanks of the Society were given to Mr. Mallet for his valuable Present.

The following Paper was read:—

“On the Integration of Algebraical Functions, with Illustrations in Mechanics.” By W. H. L. RUSSELL, F.R.S.  
Received December 17, 1874.

(Abstract.)

The profound researches of Weierstrass, of Riemann, of Clebsch, and Gordan on the higher integrals have of late attracted the attention and been the admiration of mathematicians. There is, however, this difference between these researches and the corresponding investigations in elliptic functions—in the latter we investigate the properties of the integrals themselves; in the former we investigate the properties of certain differential equations, involving these integrals, and with more than one variable. How the values of the integrals themselves are to be found from these equations is difficult to see, and at all events must be a subject of enormous complexity. Accordingly it becomes desirable to ascertain, if possible, a more simple method of evaluating the integrals themselves. This is what I have attempted in the first section of this paper. I express the values of irrational algebraic quantities by means of linear differential equations with rational coefficients, and then express their integrals by means of converging series.

In the second section I consider, to a certain extent, the inverse problem—namely, to ascertain under what circumstances linear differential equations of the second order are satisfied by irrational functions. This problem I have already considered, although in an incomplete manner, in the Proceedings of the Royal Society.

In the third section I illustrate the principles enunciated in the first section by the solution of dynamical problems. I show that the principle of *vis viva* enables us to resolve these problems to a great extent by means of hyperelliptic functions and the higher transcendents.

Altogether I venture to hope that the memoir which I have the honour to lay before the Society will be read with interest by mathematicians.

LECTURE was delivered by Prof. W. G. ADAMS, "On the Forms of Equipotential Curves and Lines of Electric Force." The following is an

ains an account of certain experimental verifications  
ical distribution in space and in a plane conducting

any point of an unlimited plane sheet due to a charge  
y other point of the plane at distance  $r$  from it is pro-  
arithmetic of the distance, and the potential due to two  
different points of the plane is the sum of the poten-  
tial charges; so that when there are two points in a  
sheet connected with the poles of a battery, as there  
flowing at those two points, one into and the other  
the potential at any point of the sheet is proportional  
to the logarithms of its distances from the two points  
the current enters and leaves the sheet.

constant for a series of points if the difference of the  
distances of each of those points from the electrodes  
is  $c$  if the ratio of the distances of each of those points

The forms of the equipotential curves may be traced out experimentally by attaching two battery-electrodes to a disk of tinfoil, and having two similar electrodes attached to a delicate galvanometer; one of these electrodes being fixed at a point through which the equipotential curve is to be drawn, the other may be moved from point to point to trace out the successive points, so that no current may pass through the galvanometer. A comparison of the experimental results with the theory shows a complete agreement.

In a large square sheet 310 millims. in diameter, with the electrodes 126 millims. apart, the curves in the centre and near the electrodes, which are drawn by pricking fine holes through the tinfoil on a sheet of paper below, are very accurately circular, and mostly coincide with circles, until the points are so far from the centre that the form of the equipotential curves is affected by the edge of the disk. In a circular disk with the electrodes on the edge subtending  $60^\circ$  at the centre, the experimental curves are shown to be accurately arcs of circles, with their centres on the line joining the electrodes.

In an unlimited sheet, when there are several electrodes by which currents enter and leave the sheet, the potential at any point is

$$A \log \left( \frac{r \ r' \ r'' \ \dots}{r_1 r_1' r_1'' \ \dots} \right),$$

where  $r, r', r'' \dots$  are the distances to the electrodes of one kind, and  $r_1, r_1', r_1''$  are the distances to the electrodes of the other kind. Taking the case of one positive electrode at the centre and four negative electrodes round it at the corners of a square, the curves are traced and are seen to be the same as the curves at the corner of a square sheet with a positive electrode at the corner and two negative electrodes on the edges; the curves are also the same for a square sheet with a positive electrode at the corner, and one negative electrode along the diagonal.

The equation for these equipotential curves is

$$r^4 = cr_1 r_2 r_3 r_4,$$

and is derived, in the case of the limited sheets, by considering that, to every electrode on the limited sheet, there corresponds an equal and like electrode at each of the electrical images of that electrode formed by the edges of the sheet. If we trace the curves for this arrangement of electrodes in the unlimited sheet, the edges of the limited sheet will be some of the lines of force; and so we may divide the sheet along these edges, without altering the form of the equipotential curves. Where an electrode and its images coincide in position, the index of  $r$  is equal to one more than the number of images.

When there are four electrodes, two of each kind on an unlimited sheet, an equipotential curve is given by the equation

$$rr' = cr_1 r_1'.$$

its lie on a circle, and the complete quadrilateral be drawn of the circles which have their centres at the intersections of the quadrilateral, and which cut the first circle at right angles. One of these circles is an equipotential curve for the four electrodes, and the force.

cut the unlimited sheet along the edge of this latter sheet, not alter the forms of the equipotential curves; and within the sheet, one electrode of each kind, the others being their electric images. The product of the distances of an electrode and its image from the edge of the disk, then the electrode and its image coincide with the equipotential curve is

$$r^2 = cr_1 r_2.$$

One electrode is at the edge and the other is at the centre of a disk. Since the electric image of the centre is at an infinite distance, the equipotential curves is

$$r^2 = cr_1.$$

An interesting case, as showing that the equipotential curves do not cut the edge of the disk at right angles. The curves around the disk are nearly ellipses of small eccentricity, with one focus at the edge; but on placing one tracing electrode at a distance

ducting liquid and placing two points, the ends of two covered wires, for battery-electrodes, at a given depth in the liquid and away from the sides and ends of the vessel, taking similar covered wires, immersed to the same depth, for galvanometer-electrodes.

For two electrodes, the equipotential surfaces will be surfaces of revolution around the straight line joining them, and so will cut any plane, drawn through this straight line or axis, everywhere at right angles.

Hence we may suppose sections of the liquid made along such planes without altering the forms of the equipotential surfaces. This shows that we may place our battery-electrodes at the side of a rectangular box containing the liquid, and with the points only just immersed below the surface of the liquid; and the equipotential surfaces will be the same as if the liquid were of unlimited extent in every direction about the electrodes.

We shall obtain the section of the equipotential surface by taking for galvanometer-electrodes two points in the surface of the liquid, keeping one fixed and tracing out points of equal potential with the other.

The potential at any point in space, due to two equal and opposite electrodes, is

$$A \left( \frac{1}{r} - \frac{1}{r_1} \right),$$

where  $r$  and  $r_1$  are the distances of the point from the electrodes; so that for an equipotential surface

$$\frac{1}{r} - \frac{1}{r_1} = \text{constant}.$$

These surfaces are cut at right angles by the curves  $\cos \theta - \cos \phi = c$ , which are also the magnetic lines of force,  $\theta$  and  $\phi$  being the angles which the distances from the electrodes make with the axis. That the lines of force in a vessel of finite size should agree with the lines of force in space, the form of the boundary of the vessel in a plane through the axis should everywhere be a line of force; but the ends of a rectangular vessel coincide very closely with certain lines of force, either when the electrodes are at the ends, or when there are two electrodes within the vessel, and two supposed electrodes at their electrical images at an equal distance outside the ends of the vessel.

The equipotential surfaces are given in this case by the equation

$$\frac{1}{r} + \frac{1}{r'} - \frac{1}{r_1} - \frac{1}{r_1'} = \text{constant},$$

and the lines of force by the equation

$$\cos \theta + \cos \theta_1 - \cos \phi - \cos \phi_1 = c.$$

The curve for which  $c=2$  coincides very closely with the ends of the box.

The equipotential surfaces were traced out in sulphate of copper and in sulphate of zinc by the following method:—

*Equipotential Curves and Surfaces, &c.* [Feb. 25,

box was taken, and the battery-electrodes attached to which could be clamped at the centre of the end of the box brought to any required point in the line joining the centre of the end of the box. The galvanometer-electrodes were small pieces which rest on the ends and side of the box, and the deflection of the electrodes was read off by a millimetre-scale placed on the top of the box.

In the case of copper experiments, covered wire with the end exposed was immersed to half the depth of the liquid; in the experiments with zinc, the zinc electrodes were just immersed below the surface of the liquid. The close coincidence between the experimental equipotential curves and the theoretical curves and surfaces in space is shown by a comparison of the numbers given in the paper for several of the curves which have been traced out; it also shows that, by reversing the current, it is easy to keep the polarization very small, and of course to keep it, on the galvanometer-electrodes.

The electrodes are parallel lines extending throughout the depth of the liquid; the equipotential surfaces are cylindrical, and their sections in the plane of the electrodes are given by the equation

$$\log(r r' \dots) - (\log r_1 r'_1 \dots) = \log c,$$

where  $r, r', \dots$  are the distances from several positive and several negative electrodes,  $r_1, r'_1, \dots$  are the distances from the points where the electrodes cut the plane of the electrodes.

ological Action of the Chinoline and Pyridine  
By JOHN G. M'KENDRICK and JAMES DEWAR,  
Communicated by J. BURDON SANDERSON, M.D.,  
received June 11, 1874\*.

It is shown that when either quinine, cinchonine, or strychnine  
is treated with caustic potash, each of these substances yield two  
series of bases, named the pyridine and chinoline series.

mice, rabbits, guineapigs, cats, dogs, and man; but as the effects were found to be similar in all of these instances, the majority of the observations were made on rabbits. After having noted the effects of chinoline, we next studied, by the same method, the action of hydrochlorates of the bases distilling off at higher temperatures, including such bases as lepidine, dispoline, tetrahiroline, &c. We then examined the pyridine series, beginning with pyridine itself, and passing upwards to bases obtained at still higher boiling-points, such as picoline, lutidine, &c. Lastly, the investigation was directed to the action of condensed bases, such as dipyridine, parapicoline, &c.; and the effects of these substances were compared with those produced by the members of the chinoline series and among themselves. So far as we could observe, there was no difference as regards physiological action between bases obtained from cinchonine and others got from tar.

## II. PHYSIOLOGICAL EFFECTS OF HYDROCHLORATE OF CHINOLINE ( $C_8H_7N HCl$ ).

The administration, by subcutaneous injection, of  $1\frac{1}{4}$  grain for every 1 pound of weight into a healthy rabbit produced the following effects:—In four or five minutes the animal appeared to become drowsy, was unwilling to move; but when pushed, locomotion was not affected. Both the pulsations of the heart and the respiratory movements were slightly increased in frequency at this stage. The drowsiness increased, and in a few minutes more the animal sank on its abdomen and remained motionless, with the eyes widely opened. It was now gently turned over on its back or side, and it remained in that unnatural position. Still later, there was complete anæsthesia. At no period was there any hyperæsthesia. Reflex functions were also in abeyance so far that they could not be excited by pinching or pricking, but irritation by a Faradic current caused feeble movements. The animal appeared to be unconscious of loud sounds. The pupil was normal as regards size, and it contracted readily when exposed to a strong light. The reflex movements of the eyelid were not lost until the animal was in a state of deep stupor from an overdose. The respirations were now much fewer in number, and of less depth than normal. The heart still acted vigorously, but the pulsations were decreased in number by about one sixth. After remaining motionless in that condition for a period of three or perhaps four hours, the rabbit slowly recovered, raised its head from the table, began to move about, and frequently ate food placed before it. It recovered completely from the dose above indicated, without any bad symptom supervening. A dose of 2 or  $2\frac{1}{2}$  grains per pound weight was usually lethal. If, at the end of three hours, the animal showed no indications towards recovery, it apparently sank in a state of profound insensibility, the heart-pulsations became feebler, and the respirations more and more shallow, until they were barely perceptible. Death ensued.

rs. J. G. M'Kendrick and J. Dewar on

is. The temperature of the body fell  $6^{\circ}$  to  $8^{\circ}$  below  
examination of the body, made immediately after death,  
ing appearances:—(1) The vessels on the surface of  
ewhat congested; the substance of the brain itself did  
crease of vascularity; (2) the lungs were congested,  
ing the borders; (3) the heart was in a state of diastole  
oured blood; (4) the veins in the mesentery and the  
e intestine were much congested; (5) the liver showed  
ng-like congestions, indicating congestion of the portal  
idneys and other abdominal and pelvic viscera were  
nce; and (7) the urine in the bladder contained no

ptoms and *post mortem* appearances, and from special  
ent, we draw the following conclusions regarding the  
rate of chinoline.

*Nervous System.*—The action is chiefly, if not altoge-  
centres, and not on the nerves or on their peripheral  
en the sciatic nerve is irritated by very feeble Faradic  
ts no diminution of sensibility, and the muscles sup-  
contract with apparently their normal energy. The  
illed by hydrochlorate of chinoline show all the pro-  
tained from a non-poisoned animal. The sympathetic  
n t usually affected to any appreciable extent, as evi-

been observed in several experiments that strychnine, subcutaneously injected into a rabbit prostrate with hydrochlorate of chinoline, is followed by its usual physiological effects. It appears, therefore, that the substance acts chiefly on the sensory and motor centres in the cerebral hemispheres, weakening or removing all consciousness of external impressions and also all voluntary acts.

2. *Action on the Respiratory and Circulatory Systems.*—In the first instance the action of the heart and the respiratory movements are increased, but afterwards they are much diminished, and death appears to be the result of these processes becoming weaker and weaker, until they cease altogether. The increased action observed, at first, is probably due to the excitement of the animal consequent on the injection of fluid beneath the skin. So soon as the substance acts through the blood on the nerve-centres, the action of both systems is weakened. We regard this weakening as due to an action on an encephalic centre, for the two following reasons:—first, because irritation of the sympathetic and pneumogastric nerves in the neck of a rabbit, completely under the influence of hydrochlorate of chinoline, produces acceleration and retardation of the heart's action respectively, as occurs in a healthy animal; and secondly, when the heart of a frog was treated, according to Coats's method, with serum containing 3 per cent. of chinoline, no effect was observed. These experiments seem to indicate clearly that the substance acts on the encephalic centres, and through them on the heart and respiratory organs. The action of the heart finally ceases, probably by its textures being supplied with only venous blood.

3. *Action in lowering the Temperature of the Body.*—It was found, in three instances in which minute differences of temperature were observed at intervals of one minute, during a period of one hour before and one hour after the subcutaneous injection of hydrochlorate of chinoline, that the substance produced a gradual and uniform fall of temperature to the extent of from six to eight degrees below the normal. In all of these instances the animal recovered from the effects, and, during recovery, the temperature slowly rose to its normal limit. This action we regard as of considerable importance. It is probably to be explained by interference with nutritional changes between the blood and the tissues, and also by the diminution, both in frequency and depth, of the respiratory movements.

### III. ACTION OF HYDROCHLORATES OF THE HIGHER BASES OF THE CHINOLINE SERIES.

#### 1. *Bases obtained by distillation between 200° and 280° C.* *Lepidine &c., C<sub>10</sub>H<sub>9</sub>N.*

These bases produced the same general action as chinoline, with the exceptions (1) that the dose required to produce a state of complete stupor was somewhat smaller than in the case of chinoline, and (2) that,

J. G. McKendrick and J. Dewar on

por had been produced, the animal was less likely to be observed that, frequently, before death, there were other of the limbs and convulsive twitchings about

ained by distillation between  $280^{\circ}$  and  $300^{\circ}$  C.

*Dispoline* &c.,  $C_{11}H_{11}N$ .

ed that the symptoms following subcutaneous injection were very different from those of chinoline. One grain for the rabbit produced, in about five minutes, apparent side movements of the head, with a tendency occasionally backwards. This condition continued for three or four minutes. The animal lay flat on its abdomen with its legs out in a state of complete unconsciousness. There were in several instances there were compulsive twitchings of the teeth, and a slight tendency to opisthotonos. The effects were smaller than in the case of chinoline. The effects were in appearing, and they had more of a spinal than of

es obtained by distillation above  $300^{\circ}$  C.

*Tetrahiroline* &c.,  $C_{11}H_{11}N$ .

more involved as we proceed upwards, until, in the highest group, we have substances producing powerful convulsions.

3. The lethal dose is smaller for the higher than for the lower members of the series.

#### IV. ACTION OF HYDROCHLORATES OF THE BASES IN THE PYRIDINE SERIES.

The physiological action of the bases of the pyridine series was next examined in the following order :—

##### 1. *Pyridine*, $C_5H_5N$ .

The hydrochlorate of this base produced no effects, even in doses of 6 grains per pound weight, other than slight excitement and acceleration of the pulse and of the respiratory movements. The animal, judging from its gait and demeanour, appeared to be in a state analogous to intoxication. It recovered without any bad effects.

##### 2. *Picoline*, $C_6H_7N$ .

The substance was employed both in the form of the base dissolved in water and as a hydrochlorate. The salt was found to be more active physiologically than the base, but the kind of action was the same. The general effect was to produce, with a dose of 3 grains per pound weight, in the first place, general excitement and a full bounding pulse. This state was followed by a drowsy condition, which did not pass, with even a dose of 6 grains per pound weight, into complete stupor. The rabbit could always be readily aroused. While in the drowsy condition, the pulse fell in frequency and volume, and the respirations became feebler\*.

##### 3. *Lutidine*, $C_7H_9N$ .

The effects were similar to those produced by picoline, only more marked. A dose of 3 grains per pound weight produced deep stupor, from which the animal could not be aroused. It remained in this condition for a period of from two to three hours. The pulsations of the heart were much reduced in volume, but only slightly in frequency; but it was clearly observable that the respirations were much less deep than in the natural condition, and they were reduced in frequency by about one third. In a case of death from a lethal dose of 4 grains per pound, there was venous congestion in all parts of the body, but the heart was still feebly pulsating. It was observed that the blood had a peculiar dark chocolate-brown appearance. Examined with the spectroscope, it showed the two bands of oxyhæmoglobin.

\* The results we have obtained differ considerably from those described by H. Vohl and H. Eulenberg in their paper on the "Physiological Action of Tobacco when used as a Narcotic, with especial reference to the Constituents of Tobacco-Smoke," *Archiv Pharm.* [2] cxlvii. 130-166.

Messrs. J. G. M'Kendrick and J. Dewar on

4. *Collidine*,  $C_8H_{11}N$ .

was still more active in its effects. With a dose of  $1\frac{1}{2}$  grain weight, the animal rapidly sank into a state of profound anaesthesia which it could not be aroused. Anaesthesia was complete. The action of the heart and the respirations became more and more feeble, and death ensued in about 20 minutes after the dose, apparently from failure of respiration. There were no twitchings or convulsions. The subcutaneous injection into a rabbit of 1-80th of a grain of collidine was followed by the usual physiological effects of that

*Higher Pyridine Bases obtained by distillation above 200° C., such as Parvoline,  $C_9H_{11}N$ , &c.*

was found to be still more active; but the effects were of the same kind as those just described. The lethal dose was found to be  $\frac{1}{2}$  grain per pound weight. In two or three minutes the animal became comatose; when pushed could move with difficulty; respirations rapid and irregular. It then lay on its side, and in four or five minutes died, apparently in an asphyxiated condition. There were no spasms or twitchings. This substance was lethal in much smaller doses than the lower bases of the chinoline series.

The series of compounds thus showed a gradual increase in physiological action. The lowest of the series produced

violently convulsed. The convulsions continued, almost without intermission, for three or four minutes, when death ensued. So far as could be observed, consciousness was not lost until immediately before death. The character of the convulsions resembled that of those produced by cinchonine or quinine, except that the tendency to backward movements, with the fore legs extended, was not so marked; they also resembled those produced by salts of the higher members of the chinoline series, but they were more severe than in the latter. The hydrochlorates of two condensed bases of this kind were employed—the first made from pyridine, and the other from picoline. The formulæ for these are:—hydrochlorate of dipyridine,  $C_{10}H_{10}N_2 \cdot 2HCl$ ; and hydrochlorate of dipicoline, or parapicoline,  $C_{12}H_{14}N_2 \cdot 2HCl$ . The latter was found to be the more active of the two, but the actions were identical in character.

## VI. GENERAL CONCLUSIONS.

1. There is a marked gradation in the extent of physiological action of the members of the pyridine series of bases, but it remains of the same kind. The lethal dose, however, becomes reduced as we rise from the lower to the higher.

2. The higher members of the pyridine series resemble, in physiological action, the lower members of the chinoline series, except (1) that the former are more liable to cause death by asphyxia, and (2) that the lethal dose of the pyridines is less than one half that of the chinolines.

3. In proceeding from the lower to the higher members of the chinoline series, the physiological action changes in character, inasmuch as the lower members appear to act chiefly on the sensory centres of the encephalon and the reflex centres of the spinal cord, destroying the power of voluntary or reflex movement; while the higher act less on these centres, and chiefly on the motor centres, first as irritants, causing violent convulsions, and afterwards producing complete paralysis. At the same time, while the reflex activity of the centres in the spinal cord appears to be so far inactive as not to be excited by pinching or pricking, it may be readily roused to action by strychnine.

4. On comparing the action of such bases as  $C_9H_7N$  (chinoline) with  $C_9H_{11}N$  (parvoline), or  $C_8H_{11}N$  (collidine) with  $C_8H_{13}N$  (conia from hemlock), or  $C_{10}H_{10}N_2$  (dipyridine) with  $C_{10}H_{14}N_2$  (nicotine from tobacco), it is to be observed that, apart from differences in chemical structure, the physiological activity of the substance is greater in those bases containing the larger amount of hydrogen.

5. Those artificial bases which approximately approach the percentage composition of natural bases are much weaker physiologically, so far as can be estimated by amount of dose, than the natural bases; but the kind of action is the same in both cases.

6. When the bases of the pyridine series are doubled by condensation, producing dipyridine, parapicoline, &c., they not only become more

The following Papers were read :—

- I. "On the Tides of the Arctic Seas.—Part VI. Tides of Port Kennedy, in Bellot Strait, in July 1859." By the Rev. SAMUEL HAUGHTON, M.D. Dublin, D.C.L. Oxon., F.R.S., Fellow of Trinity College, Dublin. Received January 20, 1875.

(Abstract.)

These observations were made on board the yacht 'Fox,' under the command of Sir Leopold M'Clintock, during his successful search for the remains of the Franklin Expedition.

The heights of the tide were observed every hour during 23 days, and the results obtained were extremely interesting.

The tides of Port Kennedy are remarkable for two points :—

1. The magnitude of the diurnal tide.
2. The solar diurnal tide is greater than the lunar diurnal tide.

The following tidal constants have been successfully determined :—

#### I. DIURNAL TIDE.

te Legendre's coefficient of the order  $m$ , and  $P_n(x)$  that  
 is required to find the value of  $\int_0^1 P_m(x) P_n(x) dx$ . We  
 the case in which  $m=n$ ; for it is an established result  
 the integral taken between the limits  $-1$  and  $1$  is then  
 and the value between the limits  $0$  and  $1$  will be half of  
 e now that  $m$  and  $n$  are different.

at

$$1, 5, \dots, (2m-1) \left( \frac{m(m-1)}{2} \right) \dots$$

is that in which one of these quantities is even and the other odd. Put, then,  $2m$  for  $m$ , and  $2n-1$  for  $n$ ; thus we have

$$\begin{aligned} & \{2m(2m+1) - (2n-1)2n\} \int_0^1 P_{2m}(x) P_{2n-1}(x) dx \\ &= \left\{ P_{2n-1}(x) \frac{dP_{2m}(x)}{dx} - P_{2m}(x) \frac{dP_{2n-1}(x)}{dx} \right\}_{x=0} \\ &= - \left\{ P_{2m}(x) \frac{dP_{2n-1}(x)}{dx} \right\}_{x=0}. \end{aligned}$$

Then by (1) we obtain finally

$$\begin{aligned} & \{2m(2m+1) - (2n-1)2n\} \int_0^1 P_{2m}(x) P_{2n-1}(x) dx \\ &= (-1)^{m+n} \frac{1 \cdot 3 \cdot 5 \dots (2m-1)}{2 \cdot 4 \dots 2m} \cdot \frac{1 \cdot 3 \dots (2n-1)}{2 \cdot 4 \dots (2n-2)}. \end{aligned}$$

This formula will be found to include the results which are given in the Philosophical Transactions for 1870, pages 579-587.

III. "On the Determination, at Sea, of the Specific Gravity of Sea-water." By J. Y. BUCHANAN, Chemist on board H.M.S. 'Challenger.' Communicated by Prof. WYVILLE THOMSON, F.R.S. Received January 22, 1875.

(Abstract.)

In the investigation of the physical condition of the ocean the accurate determination of the specific gravity of the water holds a first place. The tolerably numerous observations which have been made in this direction, in a more or less connected manner, are sufficient to prove that the density of the water varies, not only with the latitude and longitude, but also with the distance from the surface of the source from which it is taken. This difference of density depends partly on an actual difference in saltness, and partly on a difference in temperature of the water. The amount of effect due to each of these causes can be precisely stated when we know the effect of one of them, the sum of the effects of the two being given by our observations. Hence, to determine the saltness, we eliminate the effect of temperature by reducing the results to their value at one common temperature. It is also necessary that the means of obtaining the water should be of a reliable character. In estimating, therefore, the trustworthiness of the results, we must consider, first, the means used for collecting the water; second, those used for determining the relation between its weight and volume; third, the determination of

and fourth, the reduction of the results to their value at a standard temperature. These divisions of the subject are treated

Water is collected either in an ordinary canvas bucket or in one of the various kinds of metal "water-bottle," according as it is to be obtained from the surface or from depths below it. The use of the ordinary bucket requires no explanation. When water is to be obtained from depths, a "slip" water-bottle is used. This instrument is a kind of glass bottle, improved by Dr. Meyer, of Kiel, who without doubt was assisted by Messrs. Milne, of Edinburgh, who furnished those used on the "Challenger."

Water at intermediate depths is obtained in a much lighter instrument than the "slip" bottle, and a drawing and the method of using it, is fully described in the appendix, of which this is an abstract. In principle it consists of a glass bottle furnished with stopcocks at both ends. The levers by which the stopcocks are turned are connected by a straight rod, so that they can be simultaneously either open or shut, or at least at the same phase. When water is to be collected by its means, the bottle is lowered and the instrument sunk to the required depth, where it is simultaneously securely fastened to a sounding-line. The operation must be carried on without a check, owing to the peculiar construction of the apparatus. When the required depth has been

siderable delicacy is necessary for recording them. As far as I have hitherto been able to observe, they lie between the extremes 1·02780 and 1·02400; the results, therefore, to be of any value, must be correct, at least to one in the fourth decimal place. In mentioning these extremes, it must be observed that they refer to *ocean*-waters, and not to the mixtures of fresh and salt water to be found in bays and estuaries, where waters of all degrees of saltness may be found. The instrument selected was the hydrometer; and the purpose which it was to serve being of so very special a nature, I preferred to have a special instrument made for it, to making use of the hydrometer ordinarily supplied by the instrument-maker. It has a large body and fine stem, the relation in size of the one to the other, and the absolute size of both of them, having been determined beforehand by calculation, so as to obtain the requisite delicacy. It is evident that, for a hydrometer of given size, in the measure that its delicacy is increased its range is diminished. In determining the specific gravities of sea-waters both great delicacy and considerable range are required; the latter is secured, without detriment to the former, by the application of the principle of Nicholson's hydrometer. In the paper of which this is an abstract, the construction, calibration, and method of observing the instrument are minutely described and illustrated by a drawing. The description of the instrument is briefly as follows:—The stem, which carries a millimetre-scale 10 centimetres long, has an outside diameter of about 3 millimetres, the external volume of the divided portion being accurately 0·8607 cubic centimetre; the mean volume of the body is 160·15 cubic centimetres, and the weight of the glass instrument is 160·0405 grammes. With this volume and weight it floats in distilled water of 16° C. at about the lowest division (100) of the scale. In order to make it serviceable for heavier waters, a small brass table is made to rest on the top of the stem, of such a weight that it depresses the instrument in distilled water of 16° C. to about the topmost division (0) of the scale. By means of a series of six weights, multiples by 1, 2, 3, 4, 5, and 6 of the weight of the table, specific gravities between 1 and 1·03400 can be observed. It is not necessary that these weights should be accurate multiples of the weight of the table; it is sufficient if they approach it within a centigramme and their actual weight be known with accuracy. The weights of the table and weights in actual use are:—

Weight of table . . . . .	0·8360	gramme.
Weight of weight No. I. . . . .	0·8560	„
„ „ II. . . . .	1·6010	„
„ „ III. . . . .	2·4225	grammes.
„ „ IV. . . . .	3·2145	„
„ „ V. . . . .	4·0710	„
„ „ VI. . . . .	4·8245	„

the hydrometer is always used with the table and No. V. weight.

The mechanical part of the construction of the instrument was, with the exception of the closing of the top of the stem (which, when opened into a funnel-shape large enough to receive the nine weights), the calibration of the stem was effected by placing it with successive weights, and observing the consequent rise of the surface of distilled water of known temperature. This done, the top of the instrument was carefully weighed. The expansion of the glass at a given temperature was determined in a similar manner by placing the instrument in distilled water of various temperatures. The expansion of the glass was then found to be 0.000029 per cent.

The instrument at sea about 900 cubic centimetres of water in the containing cylinder placed on a swinging table, in a position as near the centre of the ship as possible. The observation with the instrument loaded with the necessary table and weight, is then made in the ordinary way, the accuracy of the readings being but little affected by pitching; pitching, however, is found to have a distinctly distorting effect, when it is in any way violent, it is advisable to store the instrument in water till the weather improves. The precautions to be observed in making these observations at sea must be sought for in the

his theory of oceanic circulation, owing to difference of density of the water in its different parts, he found the want of information on this important subject. At his request, the late Professor Hubbard, of the National Observatory, U.S., instituted a series of experiments, from which he was enabled to lay down a curve of the volumes of sea-water at all temperatures, from considerably below the freezing-point to much above what obtains even in tropical atmospheres. The results are published in Maury's 'Sailing Directions,' 1858, vol. i. p. 237, and have evidently been carried out with great care. The composition of different oceanic waters varies, even in extreme cases, within such close limits, that the law of thermal expansion is sensibly the same for all of them; of this Hubbard's experiments afford satisfactory proof. In the Table which gives the results of all his experiments he takes the volume of water at 60° F. as his unit. In order to avoid much useless calculation, I have been in the habit of reducing my results to the same temperature (15°·56 C.), while, for a like reason, I have retained the specific gravity of distilled water at 4° C. as the unit. The choice of a common temperature to which the results should be reduced, and of a unit of specific gravities, is a purely conventional matter; and in choosing the above-mentioned ones, in the first instance I was moved solely by a desire to save calculation. For every water, however, there is one temperature to which it would be natural to reduce its specific gravity—namely, the temperature which the water had when in its place in the ocean; and in this sense all my results during the cruise have been reduced. Hubbard's Table of the change of volume of a mass of sea-water with change of temperature enables us very easily to reduce any observed specific gravity from the temperature of observation to any other temperature, say 15°·56 C. In the paper it is transcribed from the 'Sailing Directions.' In the following Table the volumes for every Centigrade degree from -1° C. to +30° C. are given:—

TABLE I.

Temp. ° C.	Volume.	Temp. ° C.	Volume.	Temp. ° C.	Volume.	Temp. ° C.	Volume.
-1	0·99792	+7	0·99853	+15	0·99987	+23	1·00194
0	795	8	866	16	1·00010	24	224
+1	794	9	878	17	034	25	256
2	804	10	893	18	059	26	288
3	812	11	910	19	086	27	320
4	820	12	927	20	111	28	352
5	830	13	947	21	137	29	385
6	840	14	967	22	164	30	420

gravity of a sea-water be found to be  $y'$ , at a temperature  $t$ , the volume found in the above Table corresponding to  $t$  will have, for the value of the specific gravity reduced

$$x' = vy'.$$

For observed specific gravity  $y''$ , at the same temperature  $t$ ,  $15^{\circ}\cdot56$  C.,

$$x'' = vy''.$$

In angular coordinates, let observed specific gravities be  $y$  on the axis of  $y$ , and reduced ones, on the same scale, along the axis of  $x$ . We have then two points  $(vy', y')$  and  $(vy'', y'')$ , and the straight line passing through them is

$$y = \frac{1}{v}x.$$

This line passes through the origin and makes an angle  $\tan^{-1} \frac{1}{v}$  with the axis of  $x$ .

By giving to  $v$  the successive values found in the above Table for different temperatures, we can draw a system of lines passing through the origin, and each one representing the relation between the specific gravity of different sea-waters at  $15^{\circ}\cdot56$  C. and at the temperature of observation  $t$ . If the values of  $v$  have been taken from the above Table for every degree Centigrade, then the lines will be drawn for every degree Centigrade. In the extended

as  $14^{\circ}$  C.,  $16^{\circ}$  C., and so forth. In order to reduce results from their value, the unit being water at  $4^{\circ}$  C., to their value the specific gravity of distilled water at any other temperature being unity, it is only necessary to divide the result by the specific gravity of distilled water at this temperature, the unit being water at  $4^{\circ}$  C. Let  $x'$  be the specific gravity of a sea-water reduced to  $15^{\circ}\cdot56$ , and let it be required to convert it into its value when the unit is water at  $t^{\circ}$ . Let  $c$  be the specific gravity of distilled water at  $t$ , that at  $4^{\circ}$  C. being unity, we have then for the specific gravity with new unit

$$y' = \frac{1}{c} x' \text{ or } x' = cy'.$$

Similarly, if any other water be taken of the specific gravity  $x''$  at  $15^{\circ}\cdot56$ , its value at  $15^{\circ}\cdot56$  C., water at  $t^{\circ}$  being unity, will be

$$y'' = \frac{1}{c} x'' \text{ or } x'' = cy''.$$

And, just as before, we get the general equation to a system of lines, which, when the origin is the point  $(a, a)$ , is

$$y = \frac{1}{c} x + a \frac{1-c}{c}. \quad \dots \dots \dots (2)$$

Now in Table I. the extreme values of  $v$  are  $0\cdot99792$  and  $1\cdot00420$ , and for temperatures below  $22^{\circ}$  C. the extreme values of  $c$  are  $0\cdot99789$  and  $1$ . For any value of  $c$ , between those extremes, the line expressed by equation (2) must coincide with one represented by equation (1). By comparing, then, the values of  $v$  in Table I. with those of  $c$  in any Table of the expansion of distilled water, the lines which represent specific gravities at  $15^{\circ}\cdot56$ , their unit being water at any temperature  $t$ , may be found which correspond to isothermals represented by equation (1). For instance, the value of  $c$  for  $15^{\circ}\cdot56$  is  $0\cdot99910$ , and in Table I. the value of  $v$  for  $11^{\circ}$  C. is also  $0\cdot99910$ . For these values, then, equations (1) and (2) represent identical lines. Hence, to reduce any observed specific gravity to its value at  $15^{\circ}\cdot56$  C., water at  $15^{\circ}\cdot56$  C. being unity, the same construction is made as for reducing to  $11^{\circ}$  C., the unit remaining the same; only the intersection of the line parallel to the axis of  $y$  with the isothermal to  $11^{\circ}$  C. is taken, and the ordinate of the point is the specific gravity at  $15^{\circ}\cdot56$  C., water at  $15^{\circ}\cdot56$  C. being unity.

In a precisely similar manner we find the equation to the isothermal for specific gravities reduced to any temperature  $t$ , water

the  $c'$  being unity, to be

$$y = \frac{1}{vc} x + a. \frac{1 - vc}{vc} \dots \dots \dots (3)$$

At  $11^{\circ}$  C. we have  $v=0.99910$ ,  $c=0.99966$ , whence in Table I.  $0.99878$  is the value of  $v$  for the isothermal to reduce observed specific gravities to their values at  $9^{\circ}$  C. being unity, is equivalent to reducing it to  $9^{\circ}$  C., being unity, the isothermal for which is given in the chart. For example, let the specific gravity of a water be observed at  $15^{\circ}$  C. to be  $1.0247$ . Finding  $1.0247$  on the axis of  $y$ , we draw the line  $AB$  parallel to the axis of  $x$ . Through the point  $B$  with the isothermal for  $20^{\circ}$  C., the line  $CD$  is drawn parallel to the axis of  $y$ . The ordinates of its points of intersection with the isothermals are the specific gravities at these temperatures, being unity; they are at  $15^{\circ}.56$   $1.02575$  (both by the inter-isothermal and with the axis of  $x$ ), at  $11^{\circ}$   $1.02665$ , and when the unit is the specific gravity of distilled water the specific gravity at  $15^{\circ}.56$  is  $1.02665$ , or the same as at  $11^{\circ}$ , being unity. When the specific gravity of distilled water at  $11^{\circ}$  C. is  $1.02685$ , or the same as at  $4^{\circ}$  is unity.

Of the cruise a considerable number of waters have

JOSEPH DALTON HOOKER, C.B., President, in the Chair.

The Presents received were laid on the table, and thanks ordered for them.

The following Papers were read :—

- I. "On Traumatic Inflammation of Connective Tissue." By G. THIN, M.D. Communicated by Professor HUXLEY, Sec. R.S. Received February 6, 1875.

(Abstract.)

The author, referring to observations recorded in his previous papers, distinguishes in the cornea primary bundles of fibrillary tissue, which are covered by elongated flat cells, layers of quadrangular flat cells (which are analogous in appearance and relative position to the layers of cells described by him as investing the secondary and tertiary bundles of tendon), and the stellate cells. To these he now adds a description of parallel chains of spindle cells, each cell having two processes, one at each end of the spindle, by which it is joined to its fellows on either side. These cells are coextensive with the cornea-substance, and are present in every interspace of the primary bundles, and, consequently, layers in different planes cross each other at an angle.

They can be occasionally seen in thin vertical sections of the fresh frog's cornea, treated in osmic acid; and from such preparations a cell with its terminal processes can be sometimes isolated. They are more easily seen in similar sections which have been 15-30 minutes in half per cent. solution of chloride of gold and then sealed up in concentrated acetic acid and examined 24-48 hours afterwards.

They have no anatomical continuity with the stellate cells.

In the fresh frog's cornea examined entire in serum, the structure, looked at through the anterior epithelium, can be seen to be broken up by clefts, the borders of which have a double contour. These clefts extend from the epithelium to a varying depth into the fibrillary tissue. They are arranged sometimes concentrically, and sometimes in waving lines which give off branches which are narrower as they approach the centre of the cornea. The double-contoured borders are not parallel to the median plane of the cornea, and can be traced only by changing the focus.

From the existence of these clefts the author infers a division of the cornea-substance into compartments equivalent to the secondary and tertiary bundles of tendon.

In inflammation the clefts are much widened, and their finer ramifications become visible. In preparations of inflamed cornea different tracts

re bounded by the clefts are coloured of different shades, the difference affecting the fibrillary tissue, and more the cells.

tents of the interspaces of the inflamed cornea differ from those of the healthy cornea, inasmuch as the former contain, notably, the dark granular substance, which results from the chloride of gold.

At an early stage of inflammation (after a few hours) the distensions between the primary bundles and of the wider spaces between the lamellæ, corresponding to the effects of the action of chloride of gold; and preparations made by this reagent which show that the two kinds of lamellæ over the respective surfaces are arranged after the same manner. The cells thus seen can be identified by their arrangement as those which are isolable from the warm saturated solution of caustic potash, and which are preparations sealed up in aqueous humour.

Section occasionally permits the demonstration of the secondary bundles of tendon.

The full gold reaction, in such cases, is probably due solely to the contents of the interspaces, is inferred from the fact that, in the corneas which have died from disease and have been some

up in blood-serum, the latter method being found more certain to give available preparations.

The only appearance observed, anterior to a complete destruction of the cell, was a division of the nucleus into two or more parts. In serum preparations the products of the division assumed the form of circles of highly refractive particles. Similar particles were sparsely scattered in the substance of the cell.

The area of any one circular product of this division was always much smaller than that of the undivided nucleus.

In regard to the stellate cells, the author questions the correctness of the accepted theory, which implies an identity of the cell and its processes with the visible protoplasm. He considers that the refractive particles, which constitute what is visible in the cellular protoplasm, are suspended in a fluid, similarly to the pigment-granules in the pigment-cells as described by Mr. Lister. The phenomenon described by German investigators as "*Zusammenballen*" of the cell-processes, he attributes to a collection of the protoplasmic particles in the centre of the cell, similar to that which takes place in concentration of pigment. This opinion is borne out by a comparison of gold and osmic-acid preparations. In conditions in which, by the former process, an isolated globular body is seen, osmic-acid preparations show that the anastomosis of the thread-like processes remains complete. Reasoning analogically from the results obtained by gold in other tissues, he infers that it is what may be described as the contents of the cell and processes which stain by that method.

Treatment by osmic acid is the only reliable method by which he has obtained satisfactory preparations showing the stellate cells in the inflamed cornea. The advantages of this mode of treatment are much enhanced by subsequent staining with red aniline, which especially differentiates the protoplasm and processes. Subsequent staining by hæmatoxylin renders the nuclei visible.

The only change, except that of destructive disintegration, observed by the author as a consequence of inflammation in the stellate cells, consists in the anastomosing processes being, in gold preparations, occasionally represented by fine darkly stained lines, on which are a series of small globular swellings placed at short regular intervals, giving any one process an appearance identical with that presented by an ultimate nerve-fibrilla in a gold preparation. The same appearance is also to be seen in osmic-acid preparations, and is suggestive of points of communication between the lumen of the process and the interfibrillary space. (This is the only form in which the author has seen the processes of the stellate cells in inflamed cornea in gold preparations. They are usually invisible by that process.)

Appearances indicative of a dividing nucleus were rarely seen, and their interpretation is doubtful. Both in respect to the nucleus and the

ate cells are the most stable of all the cellular elements

yers of the superficial corneal epithelium a network of

cells can be seen in gold and hæmatoxylin prepara-  
y cornea.

the cells of this network show a very great increase  
d with their appearance in health.

roduced by inflammation in the spindle cells may be  
stages :—

s examined in serum show that the cell-protoplasm  
used in amount, and that the cell-processes can be

This stage can be observed after twelve hours' inflam-  
from slight cauterization in a winter frog. The swelling  
is often confined to one or more tracts of the cornea,  
mentioned clefts separating the area of this appearance  
ormal cornea. The area extends from the neighbour-  
ized part towards the limbus.

g of the protoplasm extends along the processes from  
er, a chain of spindle cells being often represented by  
protoplasm on which there are very slight constrictions.  
ples to osmic-acid preparations. Deep staining with

certainly in osmic-acid preparations. They are found in groups in the wider spaces, in rows in the nerve-channels and between the primary bundles (corneal tubes of Bowman), and in large numbers in the tracts between the larger bundles. They are mostly round, sometimes club-shaped, never pointed at two extremities as an elongated shuttle-shaped mass (that is, never *spindelformig*, *spießartig*). A small minority consist of a double body formed by two rounded globular masses joined by a smooth isthmus. When stained by hæmatoxylin, nuclei are found in either end, but not in the isthmus. The author infers that we have here a corpuscle in process of division.

In rabbit-cornea, in which inflammation has lasted about a week, some white corpuscles are seen with uneven contour; and bulging outwards from, or lying close beside, them are bodies evidently nuclear, and which are affected by osmic acid and subsequent staining with red aniline, in a manner identical with the red blood-corpuscles seen in blood-vessels in the same preparation. The identity of the escaped nuclei with red blood-corpuscles is shown by a comparison of their respective size, evenness, colour, and contour.

The author infers a production of red blood-corpuscles in inflammation from the nuclei of the white blood-cells.

In observations on human blood, and that of the mouse, by staining with hæmatoxylin, he has found that while the great majority of the red corpuscles do not quickly stain in a weak solution, there are some which at once stain a deep blue, and that there are white corpuscles in which a narrow protoplasmic margin encloses a deep blue nucleus similar in contour and size to the stained red corpuscles. Amongst the red corpuscles of the frog are a minority which are recognized as being red corpuscles by their size, smooth contour, and absence of granulation, but in which there is no hæmoglobin, and the nucleus quickly stains blue in solution of hæmatoxylin, like that of the white cells.

Transitions occur in which a less and less capacity of staining on the part of the nucleus takes place, *pari passu* with an increase in the colour characteristic of hæmoglobin in the body of the cell. In the fully developed red corpuscle, the nucleus stains only after it has been for some time in contact with a weak solution of hæmatoxylin.

The author has observed in the blood of the mouse foetus the nuclei of the nucleated red blood-cell escape from the larger cell, and then become indistinguishable in form and appearance from the small red corpuscles of the mature animal present in the blood under examination.

These observations, taken in connexion with the bodies that are formed in the spindle cells and white corpuscles in inflammation, support, as the author believes, the doctrine of Wharton Jones, in regard to the formation of the red blood-corpuscles.

The mode of formation of capillary blood-vessels he believes to be identical in inflamed and in foetal tissue. In studying this subject he

advantages from the use of osmic acid, with or without staining in hæmatoxylin. The stages in this formation are

The cells enlarge and contain several nuclei which can be seen within the cell, as being of a similar nature to red blood-cells. A current of blood-plasma from the nearest vessels passes, at length, into the interfibrillary space in which the spindle cells lie. The cells escape from the spindle cells into this space, where they are indistinguishable in appearance from the ordinary red blood-

cells. By the process of diapedesis the formed elements of the nearest vessels pass into this space and the circulation is established.

These observations lead the author to suppose that the fibrine of the blood collects on the outer surface of the current and forms the wall of the new vessel, and on this substratum the white blood-cells collect themselves and spread out as an epithelium.

In the capillary spaces in the inflamed cornea, in which formation of new vessels was actively taking place, the author has isolated white blood-cells in various transition stages towards the appearance and shape of the new vessel, from rapidly enlarging vessels, cells which, from their appearance, are to be taken to be transitional to that of smooth muscular fibre.

In the capillary forms, the enlarged spindle cells decrease to their

The time was given by a chronometer marked "Wiren 34," which was lent to me by the celebrated astronomer, William Döllén, of Pulkowa.

At 18<sup>h</sup> 40<sup>m</sup> M. T. the sun rose clear and brilliant over the eastern range of the Arabian hills on the valley of the Nile under very favourable conditions of sky and atmosphere, more so on this occasion than on any other morning during our stay of 20 days at Luxor. The first glance showed us the image of the planet Venus on the sun's disk in the predicted place, making progress in her path across the sun to the point of egress.

At the first observation the borders of the planet appeared jagged and ill-defined, but as the altitude increased she presented a dark disk, clearly defined on the sun. When the time of internal contact approached, the edge of the planet and the limb of the sun were both very distinct, and favourable for making accurate observations.

When the moment of internal contact drew near, I gave my utmost attention for observing the appearance of the black drop; but I could not detect it, though I could perceive with great nicety the instant of contact. The margin of the sun's limb and that of Venus were most clearly defined to my vision.

Immediately after internal contact a bright illumination manifested itself on the emerged part of Venus; this light continued bordering on the cusp for about three fourths of the time between internal contact and external contact at egress.

The following are the times shown by chronometer for contacts and phenomena :—

	h	m	s
Time at internal contact .....	20	01	02.5
Cusp of Venus illuminated .....	20	2	00
$\frac{1}{4}$ Venus emerged, cusp illuminated .....	20	7	25
Light on right side of cusp became brighter ..	20	9	00
Light on left side became fainter .....	20	15	00
Light at time of Venus's $\frac{1}{2}$ emergence .....	20	15	30
Illumination diminishing .....	20	17	00
Illumination disappeared .....	20	20	00
$\frac{3}{4}$ Venus emerged .....	20	24	00
Time of external contact at egress .....	20	29	25

I must remark that I found it a matter of considerable difficulty to note the precise instant of the last or external contact at egress, as the indentation became so extremely slight towards the planet making final egress.

The error of the chronometer was estimated to be very nearly +15<sup>m</sup> 02<sup>s</sup> 0 by preliminary calculation; hence the times of contact by my observations, corrected for mean time at Luxor, will stand thus :—

	h	m	s
Internal contact at egress .....	20	16	04.5
External contact at egress .....	20	44	27.0

en shown by Dr. Foster (Pflüger's 'Archiv,' vol. v. p. 191)  
d current applied directly to the heart of the common  
on the body) will cause an arrest of the rhythmic beat,  
ng in *diastole*.

a thus produced are altogether similar to those seen  
the heart is inhibited by stimulation of the pneumo-

Our reasons for always removing the heart from the body are as follows:—

The movements of the heart cannot be accurately observed *in situ* unless the overlying thin integument is divided and the pericardial chamber laid open. As soon as this is done the beats are seen to become very irregular. Every movement of the body influences the flow of blood to and from the heart, and every marked change in the flow affects the force and rhythm of the beat; hence observations like those we are about to record would be impossible with the heart *in situ*.

We have been unable to find any nerve in the body stimulation of which would inhibit the heart in the same way as stimulation of the pneumogastric does the vertebrate heart.

By removal of the heart from the body, therefore, we lose nothing essential.

A graphic record of each heart-beat would of course be impossible. In order to obtain a satisfactory register of our observations, we adopted the following plan. One of us acting as observer, and watching the heart through a microscope (50 to 100 diameters), signalled, by the sudden make and break of a constant current, each beat of ventricle or auricle, or of both. The make and break were recorded by a magnetic marker, as was also the application of the stimulus, on a travelling-paper, on which seconds were at the same time being marked. In this way a little practice enabled us to register with tolerable accuracy the rhythm of the beat, though we could not, of course, record the force or character of each pulsation.

Most of our observations were directed to the ventricle, and in our remarks we have only incidentally referred to the auricle.

We at first registered the auricular beats as well as the ventricular; but an increasing conviction of the independence (in an empty heart) of the movements of the two chambers, led us after a while to confine our attention to the ventricle.

The application of the current was made by one of us while the other, watching and recording the beats of the heart, was unaware of what was being done. The faithfulness of the observations was thus materially assisted.

Finding the heart of the common snail more vigorous, though smaller, than that of the edible snail, we confined our attention to the former.

The snail's heart consists, as is well known, of a thin-walled globular auricle, separated by a ring of non-contractile tissue from an oval, almost conical, fleshy ventricle. Into the former, opposite the auriculo-ventricular orifice, opens the large pulmonary vein. The latter at its apex, opposite the auricle, narrows to the large artery, which we have spoken of as the aorta. In speaking of the ventricle we shall frequently have occasion to distinguish the broader auricular end next to the auricle from the narrow aortic end, which is continuous with the aorta. In

ster and Mr. A. G. Dew-Smith on the [Mar. 18,

from the body, it is of importance, in order to secure  
beat, that the incision should be carried through the  
ade the contractile tissue of the ventricle itself.

icle is a sac, with quite thin and smooth walls, the  
n the ventricular walls bulge out largely into the cavity,  
ed that the ventricle has the same spongy structure as  
nd many other animals.

auricular nor ventricular wall can the presence of any  
ection of nerve-cells in the form of ganglia, be detected,  
specimens or in those treated with various reagents.  
tricately arranged bundles of fibres are composed of a  
emic-looking tissue, quite unlike the ordinary muscular  
y, and in many ways resembling the cardiac tissue of

thickly studded with nuclei, some of which possibly  
ernal tessellated epithelium. Other nuclei are un-  
oper nuclei of the contractile elements, and the re-  
pe of the nature of connective tissue.

n can it safely be said that they are the nuclei of nerve-  
nerve-fibres might undoubtedly, unlike vertebrate  
fibres, easily escape detection; but Mr. A. S. Lea, of  
fully examined for us the whole of both the auricle

duration. Since the eye has been our only means of judging of the characters of the contraction, it being impossible to register the movements by the graphic method, we speak with great uncertainty on this point.

The stronger the shock the more marked, within certain limits, is the contraction. The effect, of course, in any particular case will depend not only upon the absolute strength of the current, but on its strength in relation to the irritability of the heart. Thus a heart with frequent and strong beats is affected by a weak current to the same extent as is a heart beating slowly and feebly by a strong current.

The contraction or beat thus produced by a single induction-shock is generally followed by a pause, much more evident in some cases than in others. We have not been able to discover the exact conditions which determine the duration of the pause; but it seems to depend much more on the state of the heart than on the strength of the current. There appears to be no necessary relation between the amount of the contraction and the length of the consequent pause. Thus a contraction twice the strength of the normal beat is not invariably followed by a pause of twice the length of the normal diastole; it may be more than twice as great, it may be hardly greater. On this point, again, we speak with hesitation, from inability to measure accurately the force or extent of the beats.

We have thrown in the single induction-shock at all phases of the cardiac cycle, at the height of systole, immediately before and immediately after systole, in the middle of diastole, &c., but have been unable to detect any marked differences in the result. It can hardly be doubted that, whatever be the way in which the shock causes a contraction, the heart must be differently disposed towards a stimulus, according as it is about to make or has just made a beat; nevertheless we have not succeeded in observing any marked differences.

Not only has the contraction produced by a single induction-shock the general characters of a normal "beat" rather than those of a simple muscular contraction, but, as far as can be judged by the eye, the effect of the shock on the ventricle differs from the effects produced in any ordinary muscular fibre in the following respects. In passing gradually from extremely feeble to stronger currents, there is not witnessed a gradual increase of effect; on the contrary, the change is a sudden one, from apparently no effect at all to the production of a well-marked beat. This leads us to infer that the mechanism by which feeble currents produce contractions in the heart differs somewhat from that whereby contractions are caused by stimulating an ordinary muscular fibre\*. The stronger contractions, on the other hand, produced by stronger shocks, seem to share more distinctly in the characters of an ordinary muscular contraction.

\* Compare Bowditch, *Arbeiten phys. Anstalt, Leipzig*, vi. Jahrgang (1871), p. 139.

ster and Mr. A. G. Dew-Smith on the [Mar. 18,

that single induction-shocks, below a certain intensity, have no effect on the heart.

Even in single shocks, of a strength too slight to cause a contraction at all phases of the cardiac cycle, without being able to detect any variation in either the character or frequency of the beat. We are not prepared to say that absolutely no effect is produced, but that no effect is manifested by any change in the rhythm which can be detected by the recording surface, travelling half an inch a second, or by the eye. The beat which can be recognized by the eye.

When single shocks are repeated at the same phase for a long succession. Thus we have thrown in a single weak shock at the beginning of systole as well as in the middle of diastole, during many beats, without detecting any appreciable effects.

However, are the results when the weak single induction-shocks are repeated, so that two or more shocks fall within each cycle. If the shocks produces no contraction or beat, but is followed by a prolonged diastole.

A single induction-shock, too weak to produce by itself a contraction, when repeated within the cardiac cycle, a distinct inhibition of the heart.

The beat which immediately follows the prolonged diastole is a feeble one, and the beats which occur when the shocks are repeated many

The "slight quiver" recorded in the above observations does not really contradict the statement made above concerning the rapid transition from a state of rest to a full though slight beat. The transition from this quiver to a beat is quite as abrupt as that from a state of complete rest.

As far as we have seen, inhibition may be brought about whether the electrodes be placed lengthwise (one at the auricle and the other at the aorta) or sideways, or obliquely.

We have not, however, paid particular attention to the question, whether inhibition can be produced more easily in one direction than another; nor did we, in making the above observations, pay attention to the direction of the current.

It would seem, then, from the facts we have recorded, that the inhibition produced by the tetanizing current, applied directly to the ventricle of the snail's heart, is in reality the simple summation of the effects of the single induction-shocks which make up the tetanizing current.

The effect of each shock is very slight, and a single shock has rarely the power to cause a marked prolongation of the diastole; nevertheless there is an effect which lasts for some time longer than the application of the shock itself, and of such a kind that a second shock being brought to bear on the heart before the effect of the first has passed away, has a cumulative effect, and, in consequence, distinct inhibition is observed, if not always with two, at least with several shocks rapidly repeated.

Moreover this inhibitory effect, this prevention of the contraction or beat, increases with the strength of the current employed up to a certain limit, and then the action of the stimulus is suddenly reversed, and a contraction or beat is caused instead of prevented.

There seems to us to be no escape from this conclusion, that the action of the induction-shock on the tissue of the heart is of such a kind that, beginning with a certain effect (inhibition), as it increases in intensity it suddenly topples over, so to speak, and produces the directly opposite effect (contraction).

We cannot be assisted here by the favourite theory of a double mechanism of inhibition and contraction, with different exhaustibilities, even if we suppose that these mechanisms are evenly distributed all over the ventricle. All exhaustion is, as far as we know, gradual. If we suppose the inhibitory mechanism to be more easily excited and exhausted than the contractile, then in passing from weaker to stronger stimuli we must pass through a phase in which the waning inhibition is just sufficient to counteract the increasing contraction, when, consequently, no effect at all will be produced. In our results, on the contrary, we pass at once from the *maximum* of inhibition to contraction.

#### *The Effects of the Constant Current.*

Non-polarisable electrodes (a modification of Donder's pattern) were

ster and Mr. A. G. Dew-Smith on the [Mar. 18,

current was supplied by a single Daniell's or Grenet's being divided between the electrodes placed on the heart and the resistance-coils, the resistance in which could be made to vary from 100,000 ohms, and thus a very great variety of length of the current passing through the heart.

It will to begin by describing the effects produced by the current on the heart at rest, i. e. on hearts which, after removal from the body, do not exhibit any spontaneous beat.

The auricle alone was experimented with (the auricle having been removed) and the electrodes placed lengthwise, one against the auricular end and the other against the aortic end of the ventricle, a contraction took place at the making and at the breaking of the current. These two contractions differed from each other and from a normal contraction in a very distinct manner.

The contraction of the ventricle may be described as a gathering of the fluid towards the point where the long axis of the ventricle is intersected by a transverse line drawn across the ventricle's middle, accompanied by a kind of peristaltic constriction, which begins at the auricular to the aortic end, i. e. which begins at the auricular end and leaves off at the aortic end, though during the greater part of the beat the whole of the ventricle is constricted. At the end of the beat may be recognized in an ordinary beat, and

a nerve, and the support they thus afford to Pflüger's hypothesis, that the establishment of kathelectrotonus and the disappearance of anelectrotonus alone set in motion a stimulus-wave.

When the ventricle and auricle are removed together from the body, and placed between the electrodes, so that one electrode lies at the aortic end of the ventricle and the other at the pulmonary end of the auricle, the ventricle behaves, as far as the make- and break-beats are concerned, very much as if the electrodes were applied directly to the ventricle alone. Thus when the kathode is at the auricle there is a "making"-beat at the auricular end of the ventricle and a "breaking"-beat at the aorta, and *vice versa*.

We have satisfied ourselves by numerous observations that, provided the contraction of the auricle causes no *distension* of the ventricle, the condition of the one chamber of the heart has no effect on that of the other. Between the two is a small ring of a sort of connective tissue, traversed, as far as we can make out, by no nerves, which affords complete physiological isolation of the two chambers. Thus out of the body, empty of blood, auricle and ventricle are two independent organs. Hence when a current is passed in the manner described through both ventricle and auricle, each part undergoes a separate *physiological* polarization, the auricular end of the ventricle becoming kathodic or anodic as the case may be, just as if the current were applied to the ventricle alone, account being taken of the weakening of the current through the additional resistance offered by the auricle. This, at least, is the only explanation we can give of the undoubted fact, that, with some modifications to be mentioned afterwards, the effect of the constant current is the same on the ventricle with the auricle attached as on the ventricle alone.

Besides the mere occurrence of the kathodic making- and the anodic breaking-beat, there are several facts worthy of attention. These we have studied chiefly on the ventricle with the auricle attached; but we see no reason to doubt that the same facts appear when the ventricle alone is used.

When the period during which the current passes is very short, when the current is very rapidly made and broken, the two contractions are replaced by one. This contraction or beat begins at the kathode, *i. e.* is aortic or auricular according to the position of that electrode.

Here, again, is a curious parallel to the view so generally adopted in reference to the behaviour of nerves towards the constant current, *viz.* that the establishment of kathelectrotonus is a stronger stimulus than the disappearance of anelectrotonus.

When exceedingly feeble currents are employed, it frequently happens that a momentary application of the current, a rapid make and break, produces no contraction or beat. Nevertheless such a current, if applied for several seconds, will give, as usual, a kathodic making- and an anodic breaking-beat.

oster and Mr. A. G. Dew-Smith on the [Mar. 18,

a beat on a momentary application might be explained by the effect of the too rapidly succeeding break interrupt of the immediately preceding make. But, on the other hand, there is no positive indication of the possibility of such an interference (there are reasons for thinking it extremely unlikely), and the character of the kathodic beat, when it does occur with the current, distinctly opposes such a view. On the other hand, there does exist between the making of the circuit and the occurrence of the contraction, an interval easily recognizable by the eye. In the absence of any graphic method, we have been unable to measure it. We conclude, therefore, that, in order to produce the maximum effect of even the making kathodic beat, a certain time must elapse. This time is longer for weak currents than for strong; and a very weak current may be applied for a short time without producing the maximum effect not having time to develop itself, the maximum effect appearing when the action of the same current is

being allowed for the production of the beat, the strength of the making-beat will depend otherwise entirely on the strength of the current and the irritability of the tissues of the ventricle being experimented).

The anodic breaking-beat depends, however, in a pecu-

and the intervals between the beats generally become increasingly prolonged (see fig. 13).

When the current is maintained for a short time only (10 seconds), the appearance is produced as if the heart were beating during the whole time of the passage of the current (fig. 11).

The anodic breaking-beat is, as far as our observations go, always single, is never followed by a series of beats (that is, of course, when the ventricle is one which is incapable of spontaneous pulsation).

We conclude that the constant current throws the tissue in the neighbourhood of the kathode into such a condition as is favourable for the development of beats; that this effect, though taking some time for its production, reaches its maximum very soon after the making of the circuit, and thenceforward diminishes gradually.

In the neighbourhood of the anode, on the other hand, the tissue is thrown into a condition unfavourable for the production of beats, the beats which have originated in the kathodic region ceasing as they approach the anode. The rebound, however, which follows upon the breaking of the circuit develops a beat, with the occurrence of which the tissue returns to a normal condition of equilibrium, and no further beats occur.

Such are the facts which may be observed when the kathode is placed against the auricle, and the anode against the aortic end of the ventricle.

One would naturally expect that similar results, *mutatis mutandis*, would be obtained when the kathode was placed at the aortic end of the ventricle, and the anode at the auricle. Such, however, is not the case.

When the kathode is at the aorta there is only a kathodic making- and an anodic breaking-beat. Between the two the ventricle, as a general rule, remains perfectly quiet (see figs. 12 & 9). There is therefore a functional difference between the auricular and aortic ends of the ventricle.

Led by the apparent analogy of the vertebrate heart, one might be inclined to infer that there was an automatic mechanism present at the auricular end of the ventricle, but none at the aortic end.

This view, however, is directly negatived by the following facts:—

The aortic end will, in active and favourable hearts, continue to beat spontaneously for some time after being separated from the rest of the ventricle.

When, as we shall presently have occasion to mention, a spontaneously beating ventricle is submitted to the action of the constant current, the beats begin at the aortic end, and are frequently entirely confined to the aortic end when that end is made kathodic. This would be impossible if the automatic mechanism were confined to the auricular end. We have been led to connect the explanation with the shape of the ventricle

ester and Mr. A. G. Dew-Smith on the [Mar. 18,

ss of the contractile tissue of the ventricle lies towards

If the ventricle were supposed to be bisected trans-

the rhythmic impulse is generated by changes in all the  
e would naturally manifest itself first, as in fact it does,  
ed.

e the heart was first formed, each beat has been taking  
normal fashion, beginning at the auricular end. Hence  
life (let it be called what it may) of each part is habi-  
ted to such conditions as are involved in the normal  
the auricular end. One would therefore expect that,  
ual conditions, it would be easier to call forth a beat  
auricular end than at the aortic end, and that when  
ed into two pieces the auricular end would manifest a  
ore readily than the aortic end, though each end were  
ed of the power of rhythmic pulsation.

the case. The aortic end, separated from the auricular  
avourable circumstances, beat spontaneously, but will

To avoid these difficulties we have generally employed a current so weak, that a momentary application of it to the beating heart produced no appreciable result.

During the passage, however, of such a weak current very marked effects make their appearance.

Whatever the position of the electrodes, whether the current be directed longitudinally, with the kathode at the auricular end or at the aortic end, or transversely or obliquely, in all cases the normal beat is modified in such a way that the contraction begins at the kathode, and is more or less limited to the neighbourhood of the kathode. Thus, when the kathode is placed at the auricular end of the ventricle, the part immediately round the kathode contracts first, and the contraction passes down in a vermicular manner towards the anode, sometimes a very little way, sometimes a considerable distance. When the kathode is placed at the commencement of the aorta, the contractions begin at the aorta and pass upwards towards the auricular end.

Being thus partial, the beats may be said to be weaker than normal, the more so the more they are confined to the kathode. Their feebleness seems to be more evident with stronger currents (not so strong, however, as to produce an initial contraction) than with weaker ones.

We have not been able to satisfy ourselves as to any marked or constant change in the rhythm taking place.

These kathodic beats are succeeded, on breaking the current, by one or more markedly strong beats of a reverse direction, beginning at the anode and travelling towards the kathode.

In some cases the reversal has been seen to take place during the passage of the current, the last few beats beginning at the anode, but not then exhibiting the same increase of strength which is seen in the anodic beats succeeding the breaking of the current.

This last observation illustrates the fact that the effect of the constant current, like that of the tetanizing current, is at its maximum effect near the commencement, and thence declines with greater or less rapidity, the tissue becoming insensible to the current. In this case insensibility was reached after the current had been passing a very short time; and it is interesting to remark that, though the direct effect of the current thus became lost, the reaction caused by the action of the current in the first part of the period was able to manifest itself by the anodic beats.

Thus, like the initial and final beats observed when the ventricle is at rest before the application of the currents, the apparently spontaneous beats always originate at the kathode, are more or less confined to the kathodic region, and, according to the position of the electrode, may be witnessed either at the auricular or at the aortic end.

As with the heart at rest, however, so with the heart in spontaneous movement, there is a functional difference between the aortic and the auricular ends.

oster and Mr. A. G. Dew-Smith on the [Mar. 18,

is most readily observed when the ventricle with the is placed between the electrodes than when the ventricle to the action of the current, though we have observed phenomena in the latter case also.

is placed at the aorta, and the kathode at the auricle, current produces no appreciable effect, except that perhaps a feebler and somewhat quicker (fig. 5, p. 342).

ent, applied to the same heart in the opposite direction the kathode at the aorta and the anode at the auricle), the ventricle, so that it remains in diastole during the passage of the current, and resumes its beat on the broken.

is very clearly shown in fig. 7. Here advantage was as secondary rhythm (fig. 8), which we have had more opportunity of witnessing. The ventricle, after a period of to beat, at first feebly with long pauses, then more ngly. Having reached a maximum, the beats similarly as a new period of quiescence was again begun. This rhythmic beats and quiescence was observed for a long

that when the constant current (which was exceedingly as the resistance circuit only offered a single ohm, or

end while as yet the current is unable to produce the beats at the aortic end, and the result is an apparent general inhibition of the whole ventricle.

The inhibition thus produced is, as far as we can see, a distinct inhibition; that is, the heart, which previously was beating regularly, stops beating when the current is thrown into it, remains in diastole during the short time the current continues to pass through it, and resumes its beat on the current being removed.

The occurrence of inhibition is, then, here a matter of degree; it depends on the existence of a certain relation between the irritability of the ventricle and the strength of the current employed. When a stronger current is employed, the beats, while continuing to be absent at the anode, make their appearance at the kathode, and the heart, though beating quite differently from the normal, can no longer be said to be inhibited. There is no room here for any theory of a special inhibitory mechanism, except such a one as would suppose that while the automatic mechanism was exalted at the kathode and depressed at the anode, the inhibitory mechanism was by weak currents exalted at the anode and depressed at the kathode. Such a view would be either simply a clumsy expression of facts or, if any thing more, directly opposed to all our experience of the behaviour of irritable living matter towards electric currents.

We would now call attention to fig. 5. This is the same heart which was inhibited by a current passing from the auricle to the aorta, and is apparently but little affected by nearly the same strength of current passing from the aorta to the auricle. But it will be noticed that, though the throwing of the auricular end of the ventricle into a kathodic condition does not very much, if at all, increase the beat of the ventricle, the withdrawal of the current is followed by a very distinct pause ( $\alpha$ )—in fact, by an inhibition of short duration.

This pause must be due to a reaction taking place in the kathodic region. It can hardly be due to a reaction taking place at the anodic or aortic region; for, as we have already seen, reaction at the anode takes on the form of a beat or contraction. We thus get this remarkable result, that at the kathode, where the action of the current during its passage is favourable to the beat, *the after effects, which are in the way of inhibition, are more marked than the effects of the current itself, which, as far as they go, are in the way of a quickening of the beat.*

In other words, at the auricular end of the ventricle, of whose condition, by reason of its greater susceptibility, we are better able to judge than of that of the aortic end, we find that, whatever be the direction of the current, the total effect of the passage of the current is inhibitory. For when the auricular end is anodic, the current produces on that part of the ventricle a direct inhibitory effect, which the exalted (kathodic) condition of the aortic end is unable to counterbalance; and when the auricular end is kathodic, the depressed (anodic) condition of the aortic

oster and Mr. A. G. Dew-Smith on the [Mar. 18,

great increase in the total force of the beats—so that the current is manifested only, if at all, in a quickening of the after effect is distinctly inhibitory, to such an extent as to be counteracted by the reaction, in the way of exaltation, which occurs at the (anodic) aortic end. In other words, whichever its effect may be in one case by action, in the other by reaction, a sufficiently large current gives a *balance* in favour of inhibition.

Reason of the less susceptibility of the aortic end and the lighter development in that region of a rhythmic beat, to judge of what is going on in that region during the passage of the current, we may, we venture to think, assume that the effect is of fundamentally the same kind as at the auricular end—namely, that the total effect of the passage of the current would be greater in the direction of inhibition than of exaltation. A weak current, then, passed lengthwise through the ventricle, whether from aorta to auricle or from auricle to aorta, would produce an effect (when the period of reaction is included) greater than that of exaltation.

Such a current to be momentarily passed through the ventricle in any two beats, its effect therefore, as far as it went, would be during the diastole. The effect might not be very obvious; but it would be as to escape detection by itself, but it might be made

depending on the fact that the total depressing effect of the current on the rhythmically beating tissue is greater than the total exalting effect.

It may seem strange to speak of a stimulus as producing a depressing effect; but reflection will show that it is quite what ought to be expected.

We have in the foregoing contented ourselves with speaking of the tissue in the neighbourhood of the electrodes as being in a kathodic or anodic condition as the case may be. We did so because, not having examined the condition of the electric currents of the ventricle, we hesitated in using the terms *kathoelectrotonus* and *anelectrotonus*.

We know, however, that muscle is capable of being thrown, in the *intra-polar region*, into an electrotonic condition, and that (quite in accordance with all the results recorded above) this condition lasts after the removal of the current. We therefore shall probably not err in supposing that the polarization of the cardiac tissue, which is obviously a result of the constant current, is more or less allied to that kind of polarization which we call *electrotonus*.

Now the electrotonic condition of nerve or muscle differs essentially from the polarization of any dead matter in this, that it is *essentially a function of the vital activity* of the substance polarized. May we interpret this as meaning that the change in muscle or nerve which constitutes the electrotonic condition is brought about and maintained, not solely at the expense of the energy of the current, but also, perhaps chiefly, *at the expense of the energy of the tissue itself*?

If so, then we may argue that while in the normally beating heart all the energy of the tissue is used for the production of the beat, when a constant current is passed through it some of this energy, in addition to the energy of the current itself, is used in establishing *anelectrotonus* and *kathoelectrotonus*. There must therefore, as the result of the polarization, be less energy (for the time being) available for the purposes of pulsation.

The idea of the exalting influence of a stimulus arises naturally from the fact that the stimulus may, if sufficiently intense, give rise to a contraction; and it seems at first sight contradictory that one and the same thing should produce apparently exactly opposite effects.

It is very easy, however, to trace, in the beating ventricle of the snail's heart, the transition from inhibition to the production of a contraction or artificial beat.

One stage in this transition is shown in fig. 4.

Here a weak constant current passed through the ventricle longitudinally from auricle to ventricle (and thus most favourable for inhibition) caused, when the passage was momentary (*i. e.* was removed before it had time to produce its full effect, and thus was reduced, so to speak,

oster and Mr. A. G. Dew-Smith on the [Mar. 18,

below its normal strength), simply a brief inhibition, greater length of the diastole marked  $\alpha$ .

ent, allowed to act on the tissue a sufficient time for it to num effect, gave rise to a making- and breaking-beat, the g what we have called kathodic (starting from the aortic the breaking anodic (starting from the auricular end). sufficiently strong while inhibiting the auricular end to beat of the aortic end.

ent would, if sufficiently increased in strength, have been on a momentary passage, the same effect as it has in the n by prolonged passage, with this exception, that there ble beat only instead of two.

y simply varying the intensity of the current, we get or contraction.

erved that in fig. 2 the kathodic beat is followed by a the anodic beat; and a single contraction produced by application of a stronger current would show a similar causes may be regarded as partly due to the effects of —that is, to what is commonly spoken of as exhaustion; from all our preceding observations, that they are partly inhibitory effect of the current.)

the question of the effect of a current on

and, as far as we know, the heart had in each instance been treated, in some way or other, by electric currents.

We are totally unable to give any explanation of the phenomenon; and though we have tried in various ways to produce it artificially at will, have always failed to do so.

It suggests the curious inquiry whether, during the quiescent periods, the heart is absolutely at rest, or in reality executing pulsations too small to be visible. We have been unable to detect any indications of such invisible beats, and the marked length of the first and last diastole in each active phase would seem to indicate that the median portion at least of each quiescent phase is occupied by a prolonged diastole of absolute quiescence.

We might further speculate as to whether similar secondary rhythms, marked, not of course by absolute quiescence, but by a more or less pronounced rise and fall of cardiac activity, may not exist under normal circumstances—whether they may not, for instance, be diurnal phases of the heart's own nutrition; and also as to whether the normal pulse-phase may not be made up of small, more rapid, oscillations, bearing the same relation to it as it does to the larger rhythm we are speaking of.

Lastly, if the heart of the snail were a barrel-shaped organ, like that of a Tunicate, with each end equipollent to the other, instead of being a conical mass as it is, with a wholly preponderating auricular end, it is easy to see how such a secondary rhythm as the one we have described would, if started at each end of the tube at different times, produce the well-known alternating action so characteristic of the Tunicate heart.

#### *Experiments on the Hearts of other Mollusks.*

The foregoing observations on the heart of the snail were made by us together in the Physiological Laboratory at Cambridge.

During a stay at the Zoological Station at Naples, in the month of November last, Mr. Dew-Smith made several observations on the hearts of *Sepia* and *Aplysia*, with the view to ascertain whether they would behave towards electric currents in the same way as the heart of the snail. We hoped, too, they perhaps might be found more convenient for the purposes of experiment; this hope, however, was not realized.

In the first place the heart of the *Sepia*, though it will beat when removed from the body, can be got to do so with extreme difficulty, and then for a short time only. The observations consequently had to be conducted on the heart *in situ*, and for this reason, as was explained in the case of the snail, were robbed of much of their value.

Moreover the peculiar shape of the ventricle of the *Sepia's* heart, with its two aortæ and its two branchial sinuses, render it much less suitable for the purpose in hand than the more compact and simple ventricle of the snail.

Nevertheless the following results were arrived at:—

ster and Mr. A. G. Dew-Smith on the [Mar. 18,

as to divide one aorta and the branchial sinus of one  
er aorta and the branchial sinus of the other side, each  
heart continued to beat rhythmically.

cannot be a single automatic nervous centre for the ven-  
e's heart.

be discovered, the stimulation of which would produce  
heart after the fashion of the vertebrate pneumogastric.  
ed current applied directly to the ventricle did, under  
stances, produce a stoppage of the rhythm, the heart  
stole and resuming its beat on the removal of the

m-shocks and the make and break of a constant current  
uce the same effects in *Sepia* as in the snail, sometimes  
ction and sometimes having as a result a more or less

assage of a constant current exactly the same phenomena  
in the case of the snail, the beats always starting from  
travelling towards the anode. This effect could, in fact,  
e distinctly in the case of *Sepia* than of the snail. By  
odes in a proper position the course of the pulsation  
might be at pleasure reversed.

can we believe safely conclude that what we have

have been extremely interesting to have studied the action of the constant current.

*General Considerations.*

The beat of the ventricle of the snail's heart may, we venture to think, be regarded as a rhythmic movement of purely protoplasmic nature.

The constituent fibres, if fibres we may venture to call them, are not isolated like the fibres of a vertebrate voluntary muscle, but physiologically continuous; so that any change set up in any part of the ventricle can be propagated over the whole of it in the same way that a contraction-wave set going at any point in a striated fibre is propagated along the whole length of the fibre, or that a contraction-wave is propagated from the point of stimulation along a nerveless ureter. (Compare Engelmann, *Pflüger's Archiv*, ii. p. 243.)

[The ease with which the entire ventricle of the snail can be completely polarized by the constant current may be regarded as another proof of the physiological continuity of its tissue. The want of conformity between the directions of its fibres and those of the paths naturally taken by the current in passing from one electrode to the other, forbids us to suppose that the effects described above can be the combined result of a number of independently polarized fibres.]

The changes which result in the rhythmic beat take place normally in all parts of the tissue, so that any moiety of the ventricle isolated from the rest is, under satisfactory nutritive conditions, able to execute rhythmic movements. (The isolation may be mechanical, as by section, or physical, as by polarization with the constant current.)

When the ventricle is cut in half, the two halves do not necessarily beat synchronously. Each half has a rhythm of its own, which may or may not be (and in nearly every instance is not) the same in both halves. But the rhythm of each half is, under favourable circumstances, perfect and complete; and the same may be said of still smaller pieces.

Now the normal beat of the entire ventricle is a complicated act. There are in it definite sequences. Certain fibres or certain parts of the tissue begin to contract before others, and certain parts continue to contract after others have ceased to do so. The beat is not a simple contraction-wave passing uniformly from one end to the other, or radiating equally in all directions from one point, but a peculiar movement, having for its object the ejection of fluid from the cavity in the best possible manner, and is hence a coordinated movement.

The aortic half of the ventricle, separated from the auricular half, starts each of its beats quite independently of what is going on in the ventricular half, and *vice versa*. When the two are physiologically continuous, the changes in the one are determined by the changes in the other. In order that a normal beat may be fairly carried through, the auricular half must not start its contraction until the aortic half is ready to

ties, joined together—the force and character of the systole and the length of the diastole.

We would suggest that the ganglia are not automatic in function in the above sense, but simple coordinators. The contractile tissue of the frog's ventricle, arranged in bundles isolated by connective tissue, is not physiologically continuous, though each bundle formed by the opposition of branched sheathless muscular fibres may be continuous throughout itself; and the consensus we spoke of just now cannot be effected by molecular communications. Hence the existence of differentiated organs, in the form of nerves and ganglia, by means of which indications of the condition of the isolated constituents of the ventricle (and, we may add, of the isolated auricles and ventricle) are carried, *as items of a muscular sense*, to a central organ, and thus the state of each part is made common to all. In this central organ the advent and character of each beat is determined as the expression of the nutritive condition, not of the nerve-cells only, but of the contractile elements as well.

If this view of the function of automatic ganglia (which, it will be observed, is simply a modification of Sir J. Paget's conception) be correct, it is easy to understand why we have found no such organs in the physiologically continuous protoplasmic heart of the snail.

It needs no such ganglia for the carrying on of its own rhythmic beat; nor does it need them to place it *en rapport* with the rest of the body of the animal. The movements of the body determine the quantity of blood flowing to the heart; the force and rapidity of the heart's beat is in direct ratio to the quantity of blood distending its cavities; and thus a harmony is established between the movements of the body and the circulation quite sufficient for the purposes of the snail's life, without the intervention of that nervous regulative mechanism supplied to the vertebrate heart by the various cardiac ganglia, the pneumogastric, and other nerves.

#### *Résumé.*

We have seen that, in the region of the kathode, a condition which we have compared with the kathelectrotonus of nerves is set up. This condition we will not at present venture to characterize more closely than to say that it is favourable to the production of rhythmic beats. At the anode precisely the opposite effect takes place.

We have shown that both conditions require some time for their complete establishment, and that when established they at once begin to decline. Thus they speedily reach a maximum and more gradually subside.

The setting up of kathelectrotonus will, if sufficiently intense and the maximum be fairly reached, give rise to a contraction or beat. The giving way of anelectrotonus, though with less ease, will also cause a beat. Both the establishment of anelectrotonus and the disappearance of kathelectrotonus are unfavourable to the production of the rhythmic beat.

ter and Mr. A. G. Dew-Smith on the [Mar. 18,

ervations we have made, and the explanations we have  
arded as throwing any light on the working of the  
ed on the general theory of inhibition, must be deter-  
quiries. These we have already commenced, and hope  
come of our results before the Society.

SATION OF THE DIAGRAMS (pp. 342, 343).

from right to left.

**Fig. 3.** Constant current applied to a spontaneously beating ventricle.

The upper line indicates the beats of the ventricle, the middle line the application of the current. The kathode was placed at the aortic end of the ventricle, anode placed at the auricular end of the ventricle. No resistance in the resistance-shunt; consequently only the very smallest fraction of the current could have passed through the ventricle. Current made at *x* and broken at *y*.

The beat  $\alpha$  started from the aortic end, the beat  $\beta$  from the auricular end.

**Fig. 4.** The same current, applied to the same heart, under exactly similar circumstances as in fig. 3, except that the break almost instantaneously followed the make. No beat was produced, but only a lengthening of the diastole  $\alpha$ .**Fig. 5.** Effect of constant current applied to the spontaneously beating heart, the auricle still attached to ventricle. Kathode at auricle, anode at aortic end of ventricle. Resistance introduced into the resistance-shunt  $\omega$ ; consequently the very feeblest current was sent through the heart. The current is made at *x* and broken at *y*. No appreciable effect during the passage of the current, except a slight quickening of the beat. The breaking of the current is marked by the prolonged diastole at  $\alpha$ .**Fig. 6.** Example of the "secondary rhythm" of the ventricle of the snail's heart.

Shows the secondary rhythm spoken of on page 834. The last of a series of 9 beats is shown at  $\alpha$ . Then follows a pause ( $\beta$ ) for 18 seconds; then the beats recommence at  $\gamma$ , going on 9 times to  $\delta$ ; then again follows the pause  $\epsilon$ , succeeded by another series of 9 beats, commencing at  $\zeta$ .

**Fig. 7.** Inhibition of ventricle by constant current thrown in during an active period of the secondary rhythm shown in fig. 6.

Auricle still attached to ventricle, and .1 ohm introduced into the resistance-shunt. The anode at the auricle, the kathode at the aortic end of the ventricle. An instantaneous make and break, whether thrown in during the period of rest or during the period of activity, produced no effect.  $\alpha$  is the first of the series of beats succeeding a pause. On the making of the current at *x* the beats cease, but reappear at  $\beta$  upon the breaking of the current at *y*.

N.B. The point of the lever marking the ventricular beats on the upper line was not placed exactly over the point of the lever marking on the middle line the application of the current, consequently the beat  $\beta$  seems to precede the breaking of the current at *y*. In reality it succeeded it by a very short interval.

**Fig. 8.** Pulsation brought on by constant current thrown in during the resting-period of secondary rhythm.

Heart and strength of current same as in fig. 7. Kathode at auricle, anode at aortic end of ventricle. The resting-period or pause is seen commencing at  $\alpha$ , but is broken by the beat  $\beta$ , induced by the constant current, which is made at *x*; the beats continue, ceasing at  $\gamma$  when the current is broken at *y*.

**Fig. 9.** Constant current applied to the heart at rest.

Auricle still attached to the ventricle. Anode at the auricle, kathode at the aortic end of the ventricle. The resistance in the resistance-shunt amounted to 1 ohm. Otherwise the arrangements were the same as in fig. 12 &c. The beat  $\alpha$  was very faint, starting from the aortic end of the ventricle. The beats  $\beta$ ,  $\gamma$  started from the auricular end of the ventricle. This was an exceptional case, in which a beat ( $\beta$ ) appeared before the breaking of the current.

**Fig. 10.** Constant current.

Applied to heart at rest. Kathode at auricle, anode at aortic end of ventricle.

The top line indicates beat of ventricle; the middle line indicates the application of the current, made at *x* and broken at *y*. A single Daniell's cell was used. In the resistance-shunt the resistance was 1 ohm; consequently a small fraction only of the total current passed through the heart.

The beats  $\alpha$ ,  $\beta$  commenced at the auricular end of the ventricle; the beat  $\gamma$ , due to disappearance of anelectrotonus, commenced at the aortic end of the ventricle.

Fig. 11. Same arrangement as fig. 10. Resistance in the resistance-shunt 100 ohms.

The beat at  $\alpha$ , due to the instantaneous make and break at  $\epsilon$ , was normal in character, i. e. started from the auricular end of the ventricle. The beats  $\beta$ ,  $\gamma$ ,  $\delta$  also started from the auricular end. The beat  $\epsilon$  started from the aortic end of the ventricle.

Fig. 12. Constant current applied to the heart at rest.

Auricle still attached to ventricle. Anode placed at auricle, kathode at aortic end of ventricle. The whole of the current from a single Daniell's cell was sent through the heart. Otherwise the same arrangement as in figs. 10, 12, & 13.

The beat  $\alpha$ , due to the instantaneous make and break at  $\epsilon$ , was faint, starting from the aortic end of the ventricle.  $\beta$  was a stronger beat, starting also from the aortic end of the ventricle.  $\gamma$  was a strong beat, starting from the auricular end of the ventricle.

Fig. 13. Same arrangement as figs. 10 & 11.

The whole of the current from a single Daniell's cell was thrown in. The beats  $\alpha$ ,  $\beta$ ,  $\gamma$ ,  $\delta$  started from the auricular end, and  $\epsilon$  from the aortic end of the ventricle.

1875.

which have recently been published on the absorption-  
metals, first by Roscoe and Schuster and subsequently  
publish beyond all question the facts that—

the well-known line-spectra, channelled-space spectra  
the vapours of certain metals; and,

are produced by vapours which are competent to give  
not only line-spectra, but continuous spectra in the  
ed.

ture employed for the volatilization of the metals in the  
ch we have referred did not exceed bright redness, or  
iron readily melts, the range of metals examined was

We have therefore considered it desirable to extend  
to the less fusible metals, as well as to ascertain  
of those which were volatilized at the lower tempera-  
lized by the application of a greater degree of heat. For  
we employed the flame of an oxyhydrogen blowpipe.

lateral orifices were cut in the lime for the insertion of tobacco-pipe stems, through which a stream of hydrogen could be passed into the tube and receptacle.

An electric lamp (F), in connexion with a 30-cell Bunsen's battery,

was placed opposite one end of the tube, and a spectroscope (G) opposite the other. This last instrument was by Desaga, of Heidelberg, and its single prism, the angle of which was  $60^\circ$ , was capable of distinctly separating the D lines, at the same time that it enabled us to see the whole spectrum in a single field of view, an essential point in such inquiries. The magnifying-power of the telescope was 7.5 linear.

Some preliminary experiments indicated the advisability of increasing the length of the column of vapour. To effect this, a tube 30 centims. long was made in a fresh block of lime, the cavity being arranged as before; in each end a short accurately fitting iron tube, luted with a mixture of graphite and fireclay, was inserted; and the total length of the column thus became 60 centims.

The lime block (C) with its fittings was then placed in the charcoal-furnace (E), by means of which the whole could be raised to a high temperature. As soon as the block was heated to bright redness, the metal, the vapour of which was to be examined, was introduced into the cavity (C), and the flame of the oxyhydrogen blowpipe (D) was allowed to play on its upper surface, care being taken to employ an excess of hydrogen. In almost every case the metal experimented on was rapidly volatilized (the exceptions being gold and palladium). The central portion of the

to condensation, was to produce a general absorption  
t from the special effects of absorption which we now

#### DETAILS OF THE EXPERIMENTS.

##### *Silver.*

of pure metal were placed in the cavity (C) and this

*Aluminium.*

When the temperature was so high that the spectrum of the flame was visible, an absorption was suspected in the violet; and the appearance did not change on one glass end being removed.

*Zinc.*

Many experiments were made on this metal; but there are several points connected with it which require further investigation, and we therefore reserve our remarks on the spectrum of zinc for a future occasion.

*Cadmium.*

Under both conditions of thickness the vapour of cadmium gave, in the blue only, an absorption which was very decided; an absorption in the red was also noticed which had not been observed in previous experiments when a low temperature was employed.

*Manganese.*

A small quantity of this metal was prepared with great care by Mr. Bayly, one of the assistant assayers, and it gave a distinct absorption in the red and blue, with evidences of a channelled-space spectrum. In a repetition of the experiment a more distinct channelled-space spectrum was observed.

*Iron.*

The metal employed had been obtained by electro-deposition in the manner suggested by Mr. Jacobi. Its vapour gave a slight continuous absorption in the blue.

*Cobalt*

also gave a slight continuous absorption in the blue, but less than in the case of iron.

*Nickel.*

This metal behaved in the same manner as cobalt, the absorption being about equal in amount.

*Chromium.*

The amount of metal volatilized was very small, but a fine channelled-space spectrum was observed.

*Tin.*

This metal caused a considerable absorption in the blue, but less in the red, no traces of a channelled-space spectrum being visible.

*Antimony.*

In results already published it is stated that at the low temperature antimony gives a channelled-space spectrum. In the present experi-

*On the Absorption-Spectra of Metals.* [Mar. 18,

ed merely absorption in the blue; and this is the only effects at a high temperature were inferior to those at re. As the purity of the metal first employed may be reliance can be placed on these exceptional results.

*Bismuth.*

at thickness the absorption of bismuth is strikingly of iodine at a dull red heat. We have first a bank of rption in the blue with a sharp boundary on the less and then a channelled-space absorption throughout the t of the spectrum reaching to D.

*Lead.*

first caused an absorption at both ends of the spectrum; ds the whole spectrum was extinguished. As this is a e metal, special care was taken to prove that a large en was present.

*Thallium.*

ed to Mr. Crookes for a generous supply of this metal. ic green line of thallium was observed *bright*, the light of r reversed: and it may be interesting to note that the

was broken up and disappeared, leaving a continuous channelled-space spectrum.

These experiments, made at the Royal Mint, were often prolonged for many hours consecutively. They involved much furnace-work of a peculiarly trying nature; and we have much pleasure in acknowledging the assistance we received from Mr. Edward Rigg, one of the assistant assayers, who conducted many of the tedious manipulations with great skill and patience. We should also mention that the care exercised by Joseph Groves, senior fireman, in the preparation of the furnace and the lime-moulds, contributed in no small measure to the success of the experiments.

It appears to us that these experiments, conducted at the high temperature of the oxyhydrogen flame, go far to support the conclusions which were drawn from the experiments at a lower temperature. First, in passing from the liquid to the most perfect gaseous state, vapours are composed of molecules of different orders of complexity; and second, this complexity is diminished by the dissociating action of heat, each molecular simplification being marked by a distinctive spectrum. There is also an intimate connexion between the facility with which the final stage is reached, the group to which the element belongs, and the place which it occupies in the solar atmosphere.

III. "On the Liquation, Fusibility, and Density of certain Alloys of Silver and Copper." By W. CHANDLER ROBERTS, Chemist of the Mint. Communicated by Dr. PERCY, F.R.S. Received March 11, 1875.

(Abstract.)

The author states that the most remarkable physical property of silver-copper alloys is a molecular mobility, in virtue of which certain combinations of the constituents of a molten alloy become segregated from the mass, the homogeneous character of which is thereby destroyed. These irregularities of composition have long been known, and reference is made to them in the works of Lazarus Erckern (1650) and of Jars (1774). A very complete memoir was published in 1852 by Levol, who did much towards ascertaining the nature and defining the limits of this molecular mobility. He discovered the important fact that an alloy containing 71.89 per cent. of silver is uniform in composition. Its chemical formula ( $\text{Ag}_2\text{Cu}_3$ ) and peculiar structure led him to conclude that all other alloys are mixtures of this, with excess of either metal.

The electric conductivity of these alloys was studied in 1860 by Matthiessen, who doubted the accuracy of Levol's theory, and viewed them as "mechanical mixtures of allotropic modifications of the two metals in each other."

*certain Alloys of Silver and Copper.* [Mar. 18,

described the experiments he made with a view to determining the melting-points of a series of these alloys. He adopted the boiling-point of zinc ( $1040^{\circ}$  C.) as the basis of calculation, and ascertained, by the method of mixtures, the mean specific heat of wrought iron between  $0^{\circ}$  C. and the melting-point, which, as Becquerel showed, is the same as the boiling-point of zinc.

Three experiments, which were closely in accordance, were made to determine the specific heat; and it should be pointed out that this method neutralizes several errors which would affect the results of subsequent determinations.

The melting-points of several alloys were then determined by plunging a piece of the alloy into them and transferring the iron to a calorimeter. These experiments were made from  $840^{\circ}$  C. to  $1330^{\circ}$  C., or through a range of temperatures which occupy the lowest portion of the curve of fusibility for alloys containing up to 10 per cent. of silver. The results are interesting, as they show that the curves of fusibility and electric conductivity are very similar.

It is also shown that, in studying the phenomena of liquation, the use of red-hot moulds of firebrick in which the metal (about  $1000^{\circ}$  C.) is slowly and uniformly cooled. The results showed that the method of Levat's alloy is slightly disturbed by this method of cooling.

*April 8, 1875.*

JOSEPH DALTON HOOKER, C.B., President, in the Chair.

Pursuant to notice, the Right Hon. the Earl of Carnarvon and the Right Hon. William Edward Forster were balloted for and elected Fellows of the Society.

Pursuant to notice given at the last Meeting, Pierre J. van Beneden of Louvain, Joseph Louis François Bertrand of Paris, Alfred Louis Olivier Des Cloizeaux of Paris, Hippolyte Louis Fizeau of Paris, Elias Magnus Fries of Upsal, Jules Janssen of Paris, August Kekulé of Bonn, Gustav Robert Kirchhoff of Berlin, and C. Ludwig of Leipzig were balloted for and elected Foreign Members of the Society.

The Presents received were laid on the table, and thanks ordered for them.

The following Papers were read:—

- I. "First Report of the Naturalist attached to the Transit-of-Venus Expedition to Kerguelen's Island, December 1874."  
By the Rev. A. E. EATON. Communicated by the PRESIDENT.  
Received March 15, 1875.

*To the Secretary of the Royal Society.*

Royal Sound, Kerguelen's Island,  
31st December, 1874.

DEAR SIR,—It is difficult, owing to the inexactness of the charts, to inform you of the positions of the Astronomical Stations in whose neighbourhood I have been able to work in this island. The German Station is in Betsy Cove, the American at Molloy Point, Royal Sound. The English Stations also are in this Sound, the second being situated about three miles N. by W. of Swain's Haulover. The first English Station is between these last two on the mainland, six or seven miles N.W. of Three-Island Harbour, in what will be called Observatory Bay. Two days before the Transit of Venus, a party under Lieut. Goodridge, R.N., was detached from the first English Station to observe the transit from a position which he selected near the base of Thumb Peak. I have not yet been able to visit Betsy Cove.

Observatory Bay is one of the minor inlets of a peninsula comprised between two narrow arms of the sea. One of these runs up from the sound, along the western flank of the hills adjacent to Mount Crozier, several miles, and terminates at a distance of three or four hours to the north of us, and about four miles from the inlet near Vulcan Cove. The other arm, opening nine or ten miles away to the southward, proceeds

direction to within three or four miles of the former, distance from Foundry Branch.

On the shores of the sea, numerous freshwater lakes present themselves on travelling. Some in this neighbourhood are two or three miles in length, but in general they are not more than a mile long. They are shallow, and appear to be uninhabited by fish. The ice in this vicinity are not impassable, but can be traversed with every care be taken.

The principal features of the landscape are the basaltic hills, with their steep sides of rock on their sides, and broken cliffs at their summits. On the grass, their slopes are clothed with banks and boulders of *Selago*, excepting where rich damp loam affords a more luxuriant growth of the *Acacia* and the *Pringlea*. Here and there a fern (*Festuca*) grow in the interspaces of the other

Royal Sound is far warmer and drier than we were told be. In November the weather was very pleasant; but it has deteriorated, though the snow has not again covered the ground as it did when we first arrived. Probably the previous meteorology were based upon observations taken in parts where bad weather prevails; or it may be that the condition of the winter has been presumed to be constant throughout

but, probably, some of them do not cease flowering until late in the winter. When we first arrived in Royal Sound the ground was covered with snow, and scarcely any thing had begun to come out. The *Pringlea* was far advanced in bud, barely commencing to blossom. The *Acæna* was just beginning to burst into leaf. About the first week in November, *Festuca Cookii* came out, and, a few days later, *Azorella selago*. The young fronds of the ferns were just about to unroll. In the third week of the same month, *Montia fontana* and *Acæna affinis* were in flower in a sheltered spot, and *Leptinella plumosa* was first found in blossom. *Galium antarcticum* appeared about the same date. A week later, *Ranunculus hydrophilus* and a *Festuca* (*purpurascens*?) were out, and *Lycopodium clavatum* was sprouting. By the middle of the month, *Trioida* and *Lyallia kerguelensis* and also *Ranunculus crassipes* were in flower; the *Pringlea* was everywhere past flowering (excepting upon the mountains), and *Aira antarctica* began to shoot forth its panicles. Before the end of the month a *Carex* came out; but *Bulliarda* and other plants delayed still.

A few species of Mammals have been introduced into the island. Mice (evidently *Mus musculus*, L.) are common along the coast, and have been found by us in various places. The Rabbits, transported by order of the Admiralty, from the convict settlement in Table Bay have been landed by H.M.S. 'Volage' in Royal Sound. They share with the birds holes of the Petrels, and are (it is almost superfluous to mention) propagating freely. Their favourite food is the *Acæna*; but they occasionally eat *Pringlea*-leaves and gnaw away the green surface of *Azorella*. In the Crozettes, whose climate and flora are said to resemble those of this island, rabbits have become extremely abundant, and so rank and coarse that the sealers will not eat them. Goats are increasing in numbers on the leeward side of the mainland.

Whales and Porpoises occasionally enter the Sound. Old skulls of the latter, wanting the lower jaw, are cast up here and there on the beaches.

Up to the present time, I have captured only two species of Seals—a female Sea-Leopard and two males of a Platyrrhine Seal. The other kinds frequent the more open parts of the coast and islands.

Twenty-two species of birds at the fewest, perhaps twenty-three, frequent Royal Sound, viz. a *Chionis*, a Cormorant, a Teal, a Tern, a Gull, a Skua, eleven (perhaps twelve) Petrels, two Albatrosses, and three (perhaps four) Penguins. Of these I have procured eggs of the first six; also of six Petrels, one Albatross, and two Penguins. The *Thalassidromæ* are preparing for laying.

Fish are rather scarce in Observatory Bay. Only three species have hitherto occurred to us, two of which are common under stones at low water. The remains of a *Raia* have also been picked up on one of the islands by an officer of the 'Volage'; but hardly sufficient is left to enable the species to be determined. It is allied to *R. clavata* and *R. radiata*.

of the island is very interesting. Most of the larger incapable of flight. I have found representatives of Insectera, Diptera, Coleoptera, and Colembola.

comprise a species of the *Noctuina* (as I suppose) and

Of the first I have not yet reared the imago; the larva is a surface and subterranean: the adult is probably as large as a medium size. The species of *Tineina* is probably one of the most common from the form of the palpi. Its larva feeds on *Stenotaphrum*, and sometimes spins a silken cocoon for the protection of which the sexes are alike, has acute and very long antennae and the posterior pair extremely minute. In repose the wings are widely separated and almost divaricate. When the sun is active, and, if alarmed, jumps to a distance of two or three feet. During its passage through the air the wings

are represented by species of the *Tipulidæ* and *Muscidæ*. The former family. One of them is a small species of the *Tipulidæ* is abundant in mossy places, and presents no marked characters. It seems to be a degraded member of the *Tipulidæ*. It has six joints, the palpi two; the wings are ligulate and very long. It has halteres, and the female has the ovipositor enclosed in a sheath. Although it is unable to fly, it lives upon rocks in the

along the shore and also in Shag-rookeries. Its linear and very narrow wings are almost as long as the abdomen. It can jump, but cannot fly. The sexual organs are retracted.

A *Pulex* is parasitic upon *Halidroma*, and one (possibly the same species) on *Diomedea fuliginosa*.

Coleoptera are not uncommon. The larger species seem to have their elytra soldered together. There is a small species of the Brachyelytra.

Several species of *Nirmiidae* have been obtained.

Two *Podurae* (one black, the other white) are plentiful.

There appear to be few species of Spiders, though individuals are numerous. Penguins and some of the other birds are infested with Ticks. The remaining Arachnida are related to *Cribates*.

The Crustacea, Annelida, Mollusca, and Echinodermata, in this part of the island, have probably been collected by the 'Challenger' more extensively than I have been able to do; therefore I need not particularize further about them than to state that Entomostraca abound in the lakes; an earthworm is common, and a land-snail is very plentiful amongst the rocks on the hills. This last appears to appreciate comparative heat, for specimens obtained in an exposed place, during the frosty weather, were assembled together for warmth under the drip of an icicle.

In Observatory Bay, Coelenterata are not numerous. One or two species of Actiniidae on the rocks and *Macrocystis*-roots, and an Ilyanthid in mud, are the only Actinozoa I have met with. The Hydrozoa similarly have afforded only three species—a Corynid, a Campanularian, and a *Sertularella*.

There are several Sponges.

With the exception of *Limosella aquatica*, and perhaps *Agrostis antarctica*, I have obtained all the flowering plants and ferns given in the 'Flora Antarctica' as indigenous to the island. Besides these, *Ranunculus hydrophilus* and another species, a *Carex*, a *Festuca* (probably *F. purpurascens*; but I have no work containing descriptions of the flowering plants), *Polypodium vulgare*, a fern allied to *Polypodium*, and *Cystopteris fragilis* have occurred to me. There is also a plant which appears to belong to the Juncaceae. *Lycopodium clavatum* and *L. selago* are common about here. None of the Mosses, Hepaticae, or Lichens have been worked out as yet; but amongst them are one or two species of *Cladonia*, and some examples of *Lecanora paleacea*. Fungi are represented by *Agaricus* (*Psalliota*) *arvensis*, *Coprinus atramentarius*, and a peculiar parasite on *Azorella*, which grows out from the rosettes in the form of a clear jelly, which becomes changed into a firm yellowish substance of indefinite form. There are also some *Sphaeriacei* on grass and dead stems of plants. At present few additions have been made to the marine flora. The larger Algæ in Royal Sound are usually not cast upon the shore by the waves, and I have almost been entirely dependent upon grapples thrown from the rocks for specimens of the more delicate forms. *Polysiphonia Sullivanæ*

La Rue, Müller, and Spottiswoode on [Apr. 8,

*wardii* are amongst the novelties. A large number of  
anical specimens have been lost through my inability  
in time without assistance. This has principally  
of duplicates; but in one instance it has led to the  
one of the Petrels, which was the commonest bird  
e first arrived. Fortunately it is a well-known species.  
h is announced as the approximate date of our sailing  
land. Five weeks later I hope to arrive at the Cape  
you such of the specimens collected as require only  
air transmission. The more fragile things are likely to  
condition if I keep them until my return to England,  
they were sent with the others.

I am, dear Sir,

Faithfully yours,

A. E. EATON.

ts to ascertain the Cause of Stratification in  
discharges *in vacuo*." By WARREN DE LA RUE,  
MÜLLER, and WILLIAM SPOTTISWOODE. Received  
, 1875.

over the zinc rod of one cell, and drawing the silver wire of the next cell through it so as to press against the zinc. The closing of the cells by means of a cork prevents the evaporation of water, and not only avoids this serious inconvenience, but also contributes to the effectiveness of the insulation. The tubes are grouped in twenties in a sort of test-tube rack, having four short ebonite feet, and the whole placed in a cabinet 2 ft. 7 in. (78.74 centims.) high, 2 ft. 7 in. wide, and 2 ft. 7 in. deep, the top being covered with ebonite to facilitate working with the apparatus, which is thus placed on it as an insulated table.

The electromotive force of the battery, as compared with a Daniell's (gravity) battery, was found to be as 1.03 to 1\*, its internal resistance 70 ohms per cell, and it evolved 0.214 cub. centim. (0.0131 cub. inches) mixed gas per minute when passed through a mixture of 1 volume of sulphuric acid and 8 volumes of water in a voltameter having a resistance of 11 ohms. The striking-distance of 1080 elements between copper wire terminals, one turned to a point, the other to a flat surface, in air is  $\frac{3}{8}$  inch (0.096 millim.) to  $\frac{1}{8}$  inch (0.1 millim.). The greatest distance through which the battery-current would pass continuously in *vacuo* was 12 inches (30.48 centims.) between the terminals in a carbonic acid residual vacuum. This battery has been working since the early part of November 1874, with, practically, a constant electromotive force.

Besides 2000 more cells like those just described, we are putting together 2000 cells, with the chloride of silver in the form of rods, which are cast on the flattened silver wires, as in a battery described by De La Rue and Müller†, but in other respects similar to the battery above described, the glass tubes being, however, somewhat larger in diameter; the rods of chloride of silver are enclosed in tubes open at the top and bottom, and formed of vegetable parchment, the object of these vegetable-parchment cases being to prevent contact between the zinc and chloride-of-silver rods. The internal resistance of batteries so constructed is only from 2 to 3 ohms per cell, according to the distance of the zinc and chloride-of-silver rods, and they evolve from 3 to 4.5 cub. centims. (0.18 to 0.27 cub. inch) per minute, in a voltameter having a resistance of 11 ohms. Their action is remarkably constant.

For the experiments detailed below, vacuum-tubes were generally used of about  $1\frac{1}{2}$  to 2 inches (3.8 to 5 centims.) in diameter, and from 6 to 8 inches (15.24 to 20.32 centims.) long; also prolate spheroidal vessels 6 inches by 3 inches (15.24 by 7.62 centims.). The terminals are of various forms, and from 4 inches to 6 inches (10.16 to 15.24 centims.) apart, and made of aluminium and occasionally of magnesium and of palladium,

\* Compared with a Daniell's battery, in which the zinc is immersed in dilute sulphuric acid in a porous cell, its electromotive force is about 3 per cent. less than the Daniell.

† Journal of the Chem. Soc., 2nd series, vol. vi. p. 488; Comptes Rendus, 1868, p. 794.

La Rue, Müller, and Spottiswoode on [Apr. 8,

some curious phenomena with a hydrogen residual be described in a future paper. A tube which has giving results is 8 inches (20·32 centims.) long, and has platinum rings varying in diameter from  $\frac{3}{8}$  of an inch to  $\frac{1}{2}$  inch (0·95 to 3·17 centims.), the thickness of the wire being  $\frac{1}{16}$  centim.) of an inch; the rings are a little more than  $\frac{1}{4}$  inch (6 centims.) apart; and connecting wires of platinum pass from each ring and permit of the length and other conditions being varied.

Terminals of the battery were placed in connexion with different kinds—for instance, two spheres of 18 inches diameter, presenting each a superficies of 7·07 square feet (64 square decims.), and cylinders of paper covered with tinfoil, of 16 square feet (148·64 square decims.); the wires were in all cases carefully insulated. Other accumulators used of coils of two copper wires  $\frac{1}{8}$  of an inch diameter, covered with gutta percha, in two folds,  $\frac{1}{16}$  centim.) thick. One coil contains two wires, A A' and B B' side by side, each being 174 yards (159 metres) long, and the other two wires each 350 yards (320 metres) long; of the latter

selected for these experiments were those in which the stratification did not appear at all.

When the battery, already in connexion with the vacuum-tube, was also joined, as in fig. 2, on to one or more coil-condensers (coupled to introduce a greater length of wire) in the following manner, then immediately well-defined stratifications appeared in the vacuum-tube.

Fig. 2.

SZ represents the battery, V the vacuum-tube, C the coil-condenser; one terminal is connected with the end A of the wire A A', and the other terminal with the end B of the second wire B B'; connexions are also led to the wires of the vacuum-tube. The ends A' and B' are left free; and it is clear that the coil forms a sort of Leyden jar when thus used: an interval, however short it may be, must elapse in accumulating a charge which at intervals discharges itself and causes a *greater flow* in the vacuum-tube in addition to that which passes continuously. It may be stated that the capacity of the accumulator has to be carefully adjusted to prevent any cessation of the current, to avoid, in fact, a snapping discharge at distant intervals. The periodic overflows, so to speak, which increase the current from time to time, would seem to have a tendency to cause an interference of the current-waves, and to produce nodes of greater resistance in the medium, as evinced by the stratification which becomes apparent. To the eye no pulsation in the current is apparent; and in order to convince ourselves whether or not there was really any fluctuation in the current when the apparatus was thus coupled up with the battery, we made several experiments, and ultimately hit upon the following arrangement (fig. 3):—

Fig. 3.

the  $pp'$  of a small induction-coil, both with and without the  
induced into the circuit as well as the vacuum-tube  $V$  ; to  
the  $ss'$  of the induction-coil was connected a second vacuum-

secondary wire of the coil too feeble to produce any illumination. Pending the further development of our investigation, we have ventured to give an account of our progress in elucidating some points in the theory of the vacuum-discharge, without any wish to ascribe to our results more weight than they deserve.

Fig. 4.

Batteries of this description may be had from Messrs. Tisley and Spiller, Brompton Road. Their cost, in large numbers, is about one shilling per cell, exclusive of the charge of chloride of silver, which costs about two shillings per cell. The latter, either in the form of powder or of rods cast upon flattened silver wire, may be obtained from Messrs. Johnson and Matthey, Hatton Garden. When the battery is exhausted the reduced silver may be readily reconverted into chloride, with scarcely any loss.

*April 15, 1875.*

JOSEPH DALTON HOOKER, C.B., President, in the Chair.

The Presents received were laid on the table, and thanks ordered for them.

The following Papers were read:—

Development of the Teeth of Fishes (Elasmobranchii  
1)." By CHARLES S. TOMES, M.A. Communicated  
TOMES, F.R.S. Received March 1, 1875.

## (Abstract.)

It has been supposed that the whole process of the develop-  
ment in many fish might be taken to represent the earlier  
process as it is seen in man; this opinion is forcibly  
expressed by Professor Owen, who, for example, says of the sharks,  
"they present the first and transitory papillary stage of dental  
development in mammals; and the simple cartilaginous maxillary plate,  
with the groove behind containing the germinal papillæ of the teeth,  
is a magnified representation of the earliest condition of  
the mouth of the human embryo."

But, as I have already objected to by Professor Huxley, I cannot  
now concur with the statement that "in all fish the  
development of the teeth is the simple production of a soft vascular papilla from the free  
marginal membrane."

The open groove behind the jaws of cartilaginous fish is in  
fact, as it is to say, the epithelium of the jaw passes continu-  
ously over the thecal fold of mucous membrane which lies be-  
hind the developing teeth, and if the groove be

dentine-papilla, of a well-marked columnar epithelium (enamel-cells); and, behind this layer, of a sort of finely fibrous tissue with branched cells, not, however, resembling that known as the reticulum in mammalian enamel-organs.

In young specimens, before the continuity of the two structures is interrupted by the presence of a lip, the homological identity of the teeth and the dermal spines is well seen, the one passing into the other in an unbroken series; the teeth, however, even at an early period, attain to a much larger size than the contiguous dermal spines.

Amongst osseous fish, my observations have been principally made upon the perch, pike, eel, haddock, cod, mackerel, and herring.

Allowing for differences of detail, which must necessarily result from the varying configuration of the jaws, &c., the process is identical in all the fish which I have examined, and is similar to that which I have observed in reptiles.

From the oral epithelium there dips down a process, the terminal end of which becomes transformed into an enamel-organ, the contiguous subjacent tissue coincidently becoming developed into a dentine-papilla.

I have seen nothing which could be called a "free papilla;" and it is my conviction that free papillae at no time exist in any animal; but it is possible that Professor Owen's statement, that "in all fishes the first step is the simple production of a soft vascular papilla from the free surface of the buccal membrane," may have been based upon appearances such as are met with in the haddock, in which fish (in certain situations) the tissues surrounding, and lying over, the forming tooth-sac do become elevated, so that on the surface there is a papilliform eminence; this, however, is quite external to the real dentine-papilla, and is altogether extraneous to the tooth-sac, which does not make up one fourth of its bulk.

The distance from the surface at which the formation of the tooth-sac takes place seems to be variable, differing even in the same fish in different situations.

The enamel-organs of the eel and perch are peculiar, consisting mainly of the layer of "enamel-cells;" over the apex of the tooth these enamel-cells are three times as large as over its sides, the transition from cells of the one size to the other being abrupt, and not gradual.

Their teeth are surmounted by terminal caps of enamel, like those of the newts and salamanders, or those figured by Professor Owen upon the teeth of "*Ganacrodus*," a new genus founded upon this solitary character: enamel is absent from the sides of the teeth, or, if present, is in so thin a layer as to be difficult to detect with certainty.

Thus the one part of the enamel-organ appears to exercise an active function, the remainder to be rudimentary; and the position of the enamel-cells of large size coinciding with the distribution of the enamel, is, so far as it goes, evidence in favour of the hypothesis of the formation of enamel by direct conversion of the cells.

st correctly determined the homologies of the enamel-papilla, referring the first to the epithelium, the second to the follicle, however, where it exists at all, I regard the enamel as a secondary development from that region of the derm which contains the dentine-germ.

On many mammals, reptiles, and fishes lead me to the same general conclusions as to the development of teeth:—

1. The terms whatever consist, in the first instance, of two parts—the dentine-papilla and the enamel-organ.

2. The existence of an enamel-organ is wholly independent of the presence of enamel upon the teeth; examples of this have been given by Professor Turner and by myself among mammalia, among reptiles and fishes.

3. It justifies the arbitrary division into “papillary,” “follicular,” and “enamel” stages; nor does any open primitive dental groove, exist in any animal examined.

4. In all cases, an active ingrowth of a process of the oral epithelium, upwards into solid tissue, is the first thing distinguishable from the formation of a dentine-papilla, opposite to its deepest part, and *pari passu* with the development of its caecal end into

5. A capsule, or follicle, to the tooth-germ may or may not

28.6 and 12.2; when they are attached by only one combining unit, their specific volumes are 22.6 and 7.8.

Phosphorus is regarded by certain chemists as invariably a triad; others maintain that it is sometimes a triad, at other times a pentad. In the trichloride it is a triad, in the oxychloride and thiocchloride it is a pentad. According to this view, the two latter compounds possess the following constitution:—

If, however, phosphorus is invariably trivalent, the oxychloride and thiocchloride must possess the formulæ

It is possible to decide between the two modes of representing the constitution of these compounds, if it be granted that the variation in the specific volume of oxygen and sulphur is due to the manner in which these elements are held in union. For, if the phosphorus in the oxychloride and thiocchloride be quinquivalent, the oxygen and sulphur must possess the greater of the two values, since both their combining units are united to the phosphorus; if, on the other hand, phosphorus be trivalent, the oxygen and sulphur must possess the smaller of the two values.

The author has determined the specific gravity, boiling-point, and rate of expansion of  $\text{P Cl}_3$ ,  $\text{P O Cl}_2$ , and  $\text{P S Cl}_2$ , in order to ascertain the specific volume of the oxygen and sulphur in the two latter compounds, and consequently the chemical value of the phosphorus; and he finds that the specific volumes of the oxygen and sulphur are almost identical with the values given by Kopp for these elements when "without the radicle." It would therefore appear that the oxychloride and thiocchloride must possess the constitution

and that the phosphorus in these bodies is to be regarded as a triad.

The author concludes by discussing Buff's hypothesis, that the specific volume of an element varies with its chemical value; and he shows that, in the case of phosphorus, there are no reasons for the belief that this element has a variable specific volume.

"Action of Heat on the Absorption-Spectra and Constitution of Saline Solutions." By WALTER ARTLEY, F.C.S., Demonstrator of Chemistry, King's London. Communicated by Prof. STOKES, Sec. R.S. March 10, 1875.

(Abstract.)

of heat on absorption-spectra were recorded in the preliminary paper published in the *Proceedings of the Royal*

## IV.

When a simple salt assumes one or more definite states of hydration at different temperatures below  $100^{\circ}\text{C}$ ., the hydrated compounds A and B will be successively produced in the liquid state if a saturated solution of the original salt be heated to  $100^{\circ}\text{C}$ .; or, in other words, the chemical constitution of the liquid is altered so that, as higher temperatures are attained, it becomes a solution of substance A or of substance B, at intermediate temperatures mixtures of these.

## V.

The action of heat on the violet hydrated compounds of chromium is not simply a dissociation of water-molecules or of acid from base, but a true decomposition, resulting in the production of a different class of salts with different generic properties.

Many new salts were prepared for this work, and others were examined with greater care than had previously been bestowed on them; from these substances, indeed, the most important part of the results were derived.

II. "On Attraction and Repulsion resulting from Radiation."—  
Part II. By WILLIAM CROOKES, F.R.S. &c. Received  
March 20, 1875.

## (Abstract.)

This is the second part of a paper which the author sent to the Royal Society in August 1873. The author commences by describing improvements which he has made in the Sprengel pump, and in various accessories which are necessary when working at the highest rarefactions.

Continuing the description of apparatus, the author describes different new forms which enable the phenomena of repulsion by radiation to be observed and illustrated. A bulb 3 inches in diameter is blown at the end of a glass tube 18 inches long. In this bulb a fine glass stem, with a sphere or disk of pith &c. at each end, is suspended by means of a cocoon-fibre. The whole is attached to the Sprengel pump in such a way that it can be perfectly exhausted and then hermetically sealed. Besides pith, the terminals may be made of cork, ivory, metal, or other substance. During exhaustion several precautions have to be taken, which are fully entered into in the paper. To get the greatest delicacy in an apparatus of this kind, there is required large surface with a minimum of weight. An apparatus constructed with the proper precautions is so sensitive to heat, that a touch with the finger on a part of the globe near one extremity of the pith will drive the index round over  $90^{\circ}$ , whilst it follows a

a needle follows a magnet. With a large bulb, very well containing a suspended bar of pith, a somewhat striking effect is produced when a lighted candle is placed about 2 inches from the bulb. The bar commences to oscillate to and fro, the swing gradually increasing in amplitude until the dead centre is passed over, when the oscillations are made. The torsion of the suspending cord offers resistance to the revolutions, and the bar commences to oscillate in the opposite direction. This movement is kept up with great regularity as long as the candle burns.

He discusses the action of ice, or a cold substance, on the suspended bar.

Cold being simply negative heat, it is not at first sight surprising that it can produce the opposite effect to heat. The author, however, explains this by the law of exchanges, and shows that attraction is really repulsion by radiation falling on the opposite side. According to the same law, it is not difficult to foresee what will be the action of two bodies, each free to move, if they are placed in one another in space, and if they differ in temperature. The author discusses each other or from the limiting walls of the space. The author gives four typical cases, with experiments, which prove his reasoning to be correct.

He then describes experiments with the object of ascertaining whether the force of attraction, which, commencing at the neutral point, increases

very good. A ray of sunlight allowed to fall once on the pendulum will immediately set it swinging.

The form of apparatus is next described which the author has finally adopted, as combining the greatest delicacy with facility of obtaining accurate observations, and therefore of getting quantitative as well as qualitative results. It consists of a glass apparatus in the shape of an inverted T, and containing a horizontal glass beam suspended by a very fine glass thread. At the extremities of the beam are attached the substances to be experimented on, and at the centre of the beam is a small mirror from which a ray of light is reflected on to a graduated scale. The advantage which a glass thread possesses over a cocoon-fibre is that the index always comes accurately back to zero. In order to keep the luminous index at zero, except when experiments are being tried, extreme precautions must be taken to keep all extraneous radiation from acting on the torsion-balance. The whole apparatus is closely packed all round with a layer of cotton-wool about 6 inches thick, and outside this is arranged a double row of Winchester quart bottles filled with water, spaces only being left for the radiation to fall on the balance and for the index ray of light to get to the mirror.

However much the results may vary when the vacuum is imperfect, with an apparatus of this kind they always agree among themselves when the residual gas is reduced to the minimum possible; and it is of no consequence what this residual gas is. Thus, starting with the apparatus full of various vapours and gases, such as air, carbonic acid, water, iodine, hydrogen, ammonia, &c., at the highest rarefaction, there is not found any difference in the results which can be traced to the residual gas. A hydrogen-vacuum appears the same as a water- or an iodine-vacuum.

With this apparatus the effect of exposing a torsion-balance to a continuous radiation is described, and the results are shown graphically. The effect of a short (11·3 seconds) exposure to radiation is next described, and the results are given in the form of a Table.

In another Table is given the results of experiments in which a constant source of radiation was allowed to act upon one end of the torsion-beam at a distance of 140 or 280 millims., various substances being interposed. The sensitiveness of this apparatus to heat-rays appears to be greater than that of an ordinary thermo-multiplier. Thus the obscure heat-rays from copper at 100°, passing through glass, produce a deflection on the scale of 3·25, whilst under the same circumstances no current is detected in the thermo-pile. The following substances are used as screens, and the deflections produced (when the source of radiation is magnesium wire, a standard candle, copper at 400°, and copper at 100°) are tabulated:—

Rock-salt, 20 millims. thick; rock-crystal, 42 millims. thick; dark smoky talc; plate glass of various thicknesses, both white and green: a

...ning 8 millims. of water ; a plate of alum 5 millims. thick ;  
... millims. thick ; ammonio-sulphate of copper, opaque to rays  
... opaque to rays below G.

...considers that these experiments show that the repulsion  
...due to the rays usually called heat, i. e. to the extreme  
...of the spectrum. Experiments have been tried with the  
...solar spectrum formed with a quartz train, which prove  
...also exerted by the luminous and ultra violet rays. Some  
...have been obtained ; but unfavourable weather has pre-  
...observations being made with the solar spectrum.

...ric position of the neutral point dividing attraction from  
...at discussed. The position of this point varies with the  
...substance on which radiation falls, the ratio of its mass to  
...radiating and conducting-power for heat, the physical con-  
...surface, the kind of gas filling the apparatus, the intensity  
...and the temperature of the surrounding atmosphere. The  
...ed to believe that the true action of radiation is repulsion  
...e, and that the attraction observed when the rarefaction is  
...tral point is caused by some modifying circumstances  
...the surrounding gas, but not being of the nature of air-

...point for a thin surface of pith being low. and that for

perfectly exhausted apparatus, viz. it was repelled by heat of low intensity and attracted by cold. A similar experiment was next tried, only water was placed in the bulb before exhaustion. The water was then boiled away in *vacuo*, and the exhaustion continued, with frequent heating of the apparatus to dull redness, for about 48 hours. At the end of this time the bar of aluminium was found to behave exactly the same as the one in the former experiment, being repelled by radiation.

It is impossible to conceive that in these experiments sufficient condensable gas or vapour was present to produce the effects Prof. Osborne Reynolds ascribes to it. After the repeated heating to redness at the highest attainable exhaustion, it is impossible that sufficient vapour or gas should condense on the movable index to be instantly driven off by the warmth of the finger with recoil enough to drive backwards a heavy piece of metal.

While objecting to the theories already advanced as not accounting for all the facts of the case, the author confesses that he is not as yet prepared with one to put in their place. He wishes to avoid giving any theory on the subject until a sufficient number of facts have been accumulated. The facts will then tell their own tale. The conditions under which they invariably occur will give the laws, and the theory will follow without much difficulty.

#### Supplement. Received April 20, 1875.

Since the experiments mentioned in the foregoing Abstract were concluded, the author has examined more fully the action of radiation on black and white surfaces. At the highest exhaustion heat appears to act almost equally on white and on lampblackened pith, repelling them in about the same degree.

The action of the luminous rays, however, is different. These repel the black surface more energetically than they do the white surface. Taking advantage of this fact, the author has constructed an instrument which he calls a radiometer. This consists of four arms, suspended on a steel point resting on a cup, so that it is capable of revolving horizontally. To the extremity of each arm is fastened a thin disk of pith, lampblackened on one side, the black surfaces facing the same way. The whole is enclosed in a glass globe, which is then exhausted to the highest attainable point and hermetically sealed.

The author finds that this instrument revolves under the influence of radiation, the rapidity of revolution being in proportion to the intensity of the incident rays.

Several radiometers, of various constructions as regards details, but all depending on the above-named discovery, were exhibited by the author at the Soirée of the Royal Society on the 7th inst., and numerous experiments

*Attraction and Repulsion from Radiation.* [Apr. 29,

with them. The following Table, which gives the result of experiments tried with one of the first-made radiometers (and therefore less sensitive as more recent instruments), is copied from a card distributed during the evening:—

- I. "Some Particulars of the Transit of Venus across the Sun, 1874, Dec. 9, observed on the Himalaya Mountains, Mussoorie, at Mary Villa."—Note II., with Appendix. By J. B. N. HENNESSEY, F.R.A.S. Communicated by Prof. STOKES, Sec. R.S. Received January 11, 1875.

1. The instruments used were the following :—

An altazimuth by Troughton and Simms, with an azimuth circle of 8 inches diameter read by three verniers, and a complete vertical circle, also of 8 inches, read by two verniers. The circles are divided to every 10' of arc, and the verniers afford readings to 10", or by estimation to at least 5". The instrument is well provided with spirit-levels surmounted by scales. The altazimuth was used for fixing the station of observation and for determining time.

A mountain barometer.

A thermometer.

Four chronometers, viz. :—Dent 2047, used as a *journeyman* chronometer, and packed in wool in a wooden box by itself ; Barraud 885, Dent 2775, and Arnold and Dent 758, were the three *fixed* chronometers, and were placed in the same case within a room where the temperature had only a moderate diurnal range (probably under 8°). The latter case was also well padded with wool and hemp, and these chronometers were never moved between 4th and 10th December.

The equatoreal has already been sufficiently described in Note No. I.

2. The point over which the equatoreal stood is called Venus Station. Its coordinates are as follows, and were determined by angles from two known points fixed by the Great Trigonometrical Survey of India, viz. Camel's Back and Vincent's Hill Stations :—

*Venus Station.*

Latitude N. ....	30° 27' 36".3
Longitude E. of Greenwich .....	{ 78° 3' 3".2
	{ 5° 12' 12".2
Height above sea .....	6765 feet.

3. Time was determined from the zenith-distances of  $\alpha$  Tauri (east) and  $\alpha$  Aquilæ (west), when these stars were (nearly) on the prime vertical. As a rule, four pairs of zenith-distances were taken to each star—a pair consisting of one observation-instrument face east and another face west, taken in rapid succession. The chronometer-time for each observation was obtained from transits over five horizontal wires ; the resulting chronometer-error by *each* pair was computed. The journeyman chronometer was compared with the three fixed chronometers before and after observation, and the errors and rates of the latter were thus deter-

Mr. J. B. N. Hennessey on the

[Apr. 29,

in this manner, and tabulating the mean of the results of the chronometers, it was determined:—

*Mean Results.*

Chronometer-reading.			Fast on local mean time.		Daily rate.	
h	m	s	m	s		
6	47	18.5	....	1 31.3		} . . . (1)
6	48	40.6	....	1 37.7	+6.5	
6	37	19.1	....	1 45.1	+7.5	
Cloudy	....	—	....	—	+6.7	
6	42	12.1	....	1 58.6		
8	56	17.4	....	2 2.2		} +7.3
23	17	19.4	....	2 3.5		
6	37	52.6	....	2 5.8		

transit the journeyman was compared with the three before and after ingress, and also before and after applying the daily rate of +7.3, and correcting the times by the journeyman chronometer, we obtain:—

		Local mean time.			
Dec. 8.		h	m	s	
contact occurred		19	29	19.3	} . . (2)
" "		23	17	42.9	

There is, however, an incongruity in (4); for in this reduction the longitude of Venus Station is taken east of Greenwich by  $5^h 12^m 12.2^s = H$ , the *origin* for Indian longitude being adopted at  $5^h 20^m 57.8^s$  E. for Madras Observatory. In reality, however,  $H$  refers not to the *local meridian* necessarily adopted in (2), but to a concluded meridian of origin adopted for the principal triangulation of the Great Trigonometrical Survey at Kalianpur, whereas the times (2) refer to the *local meridian*, as already stated. Denoting the value of  $H$  corresponding to the local meridian by  $H_1$ , we may find (nearly)  $H_1 - H = k''$  thus:—Let  $A_0$  denote the azimuth of a terrestrial point  $P$  as determined by observations to a circumpolar star about its elongation, and  $A$ , the corresponding value as brought up by the triangulation from the concluded meridian of origin; also let  $A_0 - A = a''$ , and let  $\lambda$  stand for the latitude of  $P$ ; then it can be seen that, as a correction to (4),

$$k'' = \frac{-a''}{15} \operatorname{cosec} \lambda.$$

Now  $a''$  is not known at Venus Station; but at Banog Station, distant 2.9 miles W.N.W.,  $a'' = -14''.54$ . Adopting this value, we find  $k'' = +1''.9$ , and the *true* Greenwich mean times of contact become

	h	m	s	
1st internal contact	14	17	9.0	} . . . . (5)
2nd " "	18	5	32.6	
2nd external "	18	32	49.6	

The results (5) are given in supercession of (4).

Dehra Doon, 17th Dec., 1874.

[The "better sketch" referred to in the author's footnote to Note No. I. (p. 256) arrived in time to appear in that Note, and is, in fact, the sketch from which the woodcut on p. 257 was copied.—G. G. S.]

### "Appendix to Notes on Transit of Venus across the Sun."

Received January 11, 1875.

After posting my Note No. I., describing the phenomena I had observed at Mussoorie, I received, on 12th December, 1874, a communication from my friend the Rev. H. D. James, M.A., describing briefly what he had seen at his station of observation. In reply I made inquiry on some additional points, to which he replied on 14th inst., so that his letter has just reached me. Mr. James was located at Chakrata, on the Himalaya Mountains, at a height of 7300 feet above the sea, in lat. N.  $30^\circ 43'$ , long. E.  $77^\circ 54'$ . His station is distinctly visible from Mussoorie on a clear day. The following facts are taken from his letters above mentioned, and appear to deserve being recorded, more particularly from

at but few observers of the transit are likely to have considerable heights above the sea.

attended by his son Henry, a young gentleman with a commendable spirit of inquiry. The instrument by Smith and Beck, the property of Mr. James ; its focal length 4 feet ; at ingress, eyepiece 60-power, and its focal length 4 feet ; at egress, eyepiece 100-power, and field of view 1/2 inch. He used his pocket-watch, which has a seconds-hand. It was considerably, perhaps a minute in 12 hours."

December, 1874, Mr. James states :—

(Venus) was about halfway on (at ingress) the sun we saw a ring of white light illuminating that rim of the planet against the dark sky. When she went off we noticed the same for a much shorter time, and when only about one-third of the sun's disk."

The times of contact were as follows :—

	h	m	s
Internal contact .....	7	41	20
" " .....	11	30	15
External " .....	11	57	25

In the preceding, I wrote to Mr. James, as already mentioned, that my view resembled his ; that I had seen a ring

tact ceased, the end of the oval seemed as it were adhering to the sun's edge, and could not get free, rendering it difficult to decide when the contact ceased. Another impediment in the way of accurate timing was, that the outline of Venus looked woolly and wave-like, from a very annoying tremor in the air. Hence the notes we entered were, 'Internal contact ceased  $7^h 41^m 20^s$ , quite clear  $7^h 42^m$ .' As to the ligament which seemed to knit the two edges together, I am disposed to attribute it solely to the billowy motion of the planet's outline; for it had a hairy appearance, and sunlight could be seen through it.

"In timing the remaining contacts there was no difficulty, for as the sun arose Venus appeared to diminish in size, her outline becoming sharply defined.

"At egress the oval shape did not reappear; but just at the moment of internal contact there was a sort of flickering movement, as if the planet's edge had touched, withdrawn, and touched again. This was at  $11^h 30^m 15^s$ . At  $11^h 33^m 27^s$ , when nearly one eighth of her orb had crossed the border, its outline was for a brief while fringed with an edging of light.

"The flickering movement just mentioned, evidently an ocular illusion, induced by the eye's weariness from intent gazing, was again noticed at  $11^h 57^m 25^s$ , when the external contact ceased."

Writing again on 15th December, 1874, Mr. James enclosed the sketch given in margin, remarking in his letter, "What I meant to express by 'ligament,' was the point of connexion formed by the boundary line itself, which appeared adhesive and at the same time hairy. The dots I have placed at the point are *within* the line. I saw no 'black drop,' if by that is intended any thing beyond and attached to the boundary line of Venus. I should therefore have expressed myself more accurately if, instead of 'ligament,' I had written 'the point of apparent adhesion looked hairy.'"

It will be seen that both Mr. James and I observed an edging of light around the dark limb of Venus, and that we agree that it was quite distinct at ingress and less plain at egress. I saw this edging decidedly as an *annulus*, and, as stated in Note No. I., it was continued round the bright limb. The complete ring thus presented to view was plainly a visible

As Venus appeared at  $7^h 41^m 20^s$ , as the internal contact was in the act of ceasing.

As Venus appeared at  $7^h 41^m 20^s$ , as the internal contact was in the act of ceasing.

Mr. W. H. Cripps on a

scope. Notwithstanding the somewhat conflicting  
have appeared since writing my Note No. I., as to  
at certain stations, and pending the authoritative  
hereafter be pronounced, it appears to me probable  
n, inferiority of instruments, insensibility of eye  
shadows, and other causes, are likely to conspire  
ligament (or *pear-drop*) at the internal contacts,  
atmosphere or envelope around the planet to afford

74.

tinuous Self-registering Thermometer." By  
CRIPPS. Communicated by Prof. STOKES,  
received March 17, 1875.

paper is to explain the working of a continuous self-  
eter, the detail of which I have been for some years  
fect, though it is only recently that I have brought  
e perfection necessary for practical demonstration.  
my imperfections in the instrument, but trust that  
al after some further experiments. The object of

him, acting upon mercury in an open tube, his instrument must be regarded more as a *barometer* than as a means of measuring the temperature of the atmosphere.

My instrument is divided into two portions :—1st, the thermometer, which marks the degrees ; 2ndly, the clockwork, which indicates the hours and minutes.

The thermometer shall be first described. The form in which it was originally made, and which perhaps serves best for illustrating the principle, was the following :—

A glass bulb, rather more than an inch in diameter, ends in a glass tube 12 inches long, having a bore of  $\frac{1}{8}$  inch. This tube is coiled round the bulb in such a manner as to form a complete circle 4 inches in diameter, the bulb being in the centre of this circle.

Fixed to opposite poles of the bulb, exactly at right angles to the encircling tube, are two needle-pointed pivots. These pivots work in minute metal depressions fixed to the sides of two parallel uprights.

It will be seen from this arrangement that the bulb with its glass tube will rotate freely between the uprights, and the pivots will be the centre of a circle, the circumference of which is formed by the glass tube.

The bulb is filled with spirit in such quantity that at 60° Fahrenheit the spirit will fill not only the bulb, but about 4 inches of the tube. Mercury is then passed into the tube till it comes into contact with the spirit, and in such quantity as to fill up about 3 inches of the remaining portion of the tube.

The spirit is now heated to 120°, and as it expands forces the column of mercury in front of it till the mercury comes within  $\frac{1}{8}$  inch of the end of the tube. The tube is then hermetically sealed, enclosing a small quantity of air.

If the thermometer be now arranged with its needle-points between the uprights, it will be observed that, as the spirit contracts on cooling, it draws the column of mercury with it. This immediately alters the centre of gravity, and the bulb and tube begin to revolve in a direction opposite to that of the receding mercury.

On again applying heat, and the mercury passing forwards, the bulb regains its original position.

By this simple arrangement, the two forces, heat and gravity, acting in contrary directions, generate a beautifully steady rotatory movement.

The method by which this movement is made serviceable for moving the register will now be described.

A grooved wheel, 2 inches in diameter, is fixed to one of the central pivots, therefore revolving with the bulb. Directly above and at a distance of 7 inches from this wheel is fixed between needle-points another wheel of exactly similar size. Around and between these two wheels passes a minute endless chain.

*Continuous Self-registering Thermometer.* [Apr. 29,

fixed a tiny pencil, which will be carried backwards  
between the wheels in a perpendicular line.

The register worked by the thermometer.

A portion of the machine is so arranged that it causes a  
cylinder of 4 inches diameter and 5 inches in length, to revolve  
Round this cylinder is fixed a piece of paper 12 inches

On the paper in the direction of its greatest length  
 $\frac{1}{10}$  inch apart, each indicating  $1^{\circ}$  Fahrenheit. Across  
at right angles to these lines, are ruled twenty-four lines in  
the hours; between these three others, more lightly  
quarters. The cylinder is so placed that, as it revolves,  
the paper is  $\frac{1}{10}$  of an inch away from the point of the  
pencil being at right angles to its surface.

The pencil is connected with the clockwork in such a manner that  
(or oftener if required) it gives the pencil a gentle tap,  
pressing it against the paper.

All friction of the moving pencil against the paper is  
removed. The index is marked by a series of dots.

Which I bring before the Society, the arrangement of the  
modified, for a spiral coil of glass tube is made to take  
the place of the bulb. This means not only is a larger surface of the spirit  
exposed, making the thermometer more delicate, but also all  
the liquid drawn into the bulb is abstracted.

commonly employed by others. Great advantages have been found, however, to result from the adoption of the equal temperament (E. T.) semitone, which is  $\frac{1}{2}$  of an octave, as the unit of interval. It is the unit most familiar to musicians, and has been found to admit of the expression of the theory of cyclical systems by means of formulæ of the simplest character. The writer therefore devised the following rules for the transformation of ratios into E. T. semitones and *vice versa*, and subsequently found that De Morgan had given rules for the same purpose which are substantially the same (Camb. Phil. Trans. vol. x. p. 129). The rules obviously depend on the form of  $\log 2$ . The form of the first rule affords a little more accuracy than De Morgan's.

Rule I. To find the equivalent of a given vibrations-ratio in E. T. semitones,

Take  $\log(\text{ratio})$ , subtract  $\frac{1}{300}$ , and call this the first improved value. From  $\log(\text{ratio})$  subtract  $\frac{1}{300}$  of the first improved value and  $\frac{1}{10,000}$  of the first improved value. Multiply the remainder by 40. We can rely on five places in the result.

The following data are introduced here; they can be verified by numbers given in Woolhouse's tract:—

$$\text{Fifth} = 7.019,550,008,654.$$

$$\text{Third} = 4 - .136,862,861,351.$$

Five places are ordinarily sufficient.

Rule II. To find the vibrations-ratio of an interval given in E. T. semitones.

To the given number add  $\frac{1}{300}$  and  $\frac{1}{10,000}$  of itself. Divide by 40. The result is the logarithm of the ratio required. We can rely on five places in the result, or on six, if six are taken.

*Ex.* The E. T. third is 4 semitones. The vibrations-ratio found as above is 1.259921.

Hence the vibrations-ratio of the E. T. third to the perfect third is very nearly 126:125.

#### *Definitions.*

*Regular systems* are such that all their notes can be arranged in a continuous series of equal fifths.

*Regular cyclical systems* are not only regular, but return into the same pitch after a certain number of fifths. Every such system divides the octave into a certain number of equal intervals.

*Error* is deviation from a perfect interval.

*Departure* is deviation from an E. T. interval.

Mr. R. H. M. Bosanquet on the

When upwards are called positive, taken downwards, nega-

is said to be of the  $r$ th order, positive or negative, when the  
fifths is  $\pm r$  units of the system.

*Intervals formed by Fifths.*

When intervals of fifths are spoken of, it is intended that octaves be  
the result of a number of fifths is expressed in E. T.  
multiples of 12 (octaves) are cast out. Representing the  
system by  $7 + \delta$ , where  $\delta$  is the departure of one fifth  
from 7 E. T. semitones, we form the following intervals amongst

$$12 \text{ fifths} = 12\delta$$

$$2 \times (7 + \delta) = 84 + 12\delta, \text{ and } 84 \text{ is cast out).}$$

$$e = 2 + 2\delta$$

$$2 \times (7 + \delta) = 14 + 2\delta, \text{ and } 12 \text{ is cast out).}$$

$$\text{semitone, formed by seven fifths up,} = 1 + 7\delta$$

$$7 \times (7 + \delta) = 49 + 7\delta, \text{ and } 48 \text{ is cast out).}$$

$$\text{semitone, formed by five fifths down,} = 1 - 5\delta$$

*Regular Cyclical Systems.*

The importance of regular cyclical systems arises from the infinite freedom of modulation in every direction which is possible in such systems when properly arranged; whereas in non-cyclical systems required modulations are liable to be impossible, owing to the demand for notes lying outside the material provided.

*Theorem i.* In a regular cyclical system of the  $\pm r$ th order the difference between the seven-fifths semitone and five-fifths semitone is  $\pm r$  units of the system, or  $s - f = \pm r$  units.

Recalling the definition of  $r$ th order ( $12\delta = \pm r$  units), the proposition follows from Th.  $\beta$ .

*Cor.* This proposition, taken with Th.  $\alpha$ , enables us to ascertain the number of divisions in the octave in systems of any order, by introducing the consideration that each semitone must consist of an integral number of units. The principal known systems are here enumerated:—

*Primary (1st order) Positive.*

7-fifths semitone = $x$ units.		5-fifths semitone = $y$ units.		Number of units in octave (Th. $\alpha$ ) $5x + 7y = n$ .
2	.....	1	.....	17
3	.....	2	.....	29
4	.....	3	.....	41
5	.....	4	.....	53
6	.....	5	.....	65

*Secondary (2nd order) Positive.*

11	.....	9	.....	118
----	-------	---	-------	-----

*Primary Negative.*

1	.....	2	.....	19
2	.....	3	.....	31

*Secondary Negative.*

3	.....	5	.....	50
---	-------	---	-------	----

*Theorem ii.* In any regular cyclical system, if the octave be divided into  $n$  equal intervals, and  $r$  be the order of the system, the departure of each fifth of the system is  $\frac{r}{n}$  E. T. semitones.

For departure of 12 fifths =  $12\delta = r$  units by definition and the unit =  $\frac{12}{n}$  E. T. semitones;

$$\therefore \delta = \frac{r}{n}.$$

*Theorem iii.* If, in a system of the  $r$ th order, the octave be divided into

Mr. R. H. M. Bosanquet on the

$r + 7n$  is a multiple of 12, and  $\frac{r+7n}{12}$  is the number of  
of the system.

number of units in the fifth,

$$\delta = 7 + \frac{r}{n};$$

$$\therefore \phi = \frac{7n+r}{12},$$

or by hypothesis; whence the proposition.

From the proposition we can deduce corresponding values of  $n$   
used in the investigation of systems of the higher orders.  
Multiples of 12, where necessary, from  $n$  and  $r$ , we have the  
relations between the remainders:—

2	3	4	5	6	7	8	9	10	11
10	3	8	1	0	11	4	9	2	7

If a system divide the octave into  $n$  equal intervals, the  
sum of all the  $n$  fifths of the system  $= r$  E. T. semitones, where  
the system.

$$= \frac{r}{n}; \text{ whence}$$

An instructive illustration may be made as follows; it requires too large dimensions for convenient reproduction here:—

Set off on the axis of abscissæ the equal temperament series in order of fifths, as above, taking about 10 complete periods. If the distances of the single terms are made 1 centimetre, this will take 1<sup>m</sup>.20 in length, starting from the origin on the left.

Select a unit for the E. T. semitone of departure, say 1 decimetre.

Rule a series of lines parallel to the axis of abscissæ, at distances representing integral numbers of E. T. semitones, both above and below.

Rule, parallel to the axis of ordinates, straight lines through the points representing the E. T. notes.

Enter on the intersections the names of the E. T. notes they represent. Thus the notes on the positive ordinate of *c* are *c-c#-d . . .*, and so on, each pair separated by 1 decimetre, and the notes on the negative ordinate of *c* are *c-b-bb . . .*

If we then join the *c* on the left hand of the axis of abscissæ to all the other *c*'s on the figure, except, of course, those on the axis, we obtain a complete graphic representation of all the systems whose orders are included. The *r*th order is represented by lines drawn to the *c*'s in the *r*th line above, the  $-r$ th by the lines drawn to the *c*'s in the *r*th line below.

This illustration brings specially into prominence the singularity of multiple systems, as all the multiples of any system lie on the same straight line with it, and the representation fails to give all the notes of such systems.

#### *Multiple Systems.*

Multiple systems are such that the number of divisions in the octave (*kn*) in any such system is a multiple (*k*) of the number of divisions (*n*) of some other system.

Multiple systems have not been as yet practically applied.

These systems are not strictly regular; for though their fifths are all equal, yet they do not form one continuous series, but several. They are strictly cyclical, i. e. they divide the octave into *n* equal intervals.

*Theorem v.* A multiple system, *kn*, may be regarded as being of order *kr*, where *n* is a system of order *r*.

For, *n* being a system of order *r*,  $r+7n$  is a multiple of 12;  $\therefore$  also  $k(r+7n)$  is a multiple of 12, which is the condition that the system *kn* be of order *kr*.

This is useful in the investigation of systems of the higher orders.

If *n* is a multiple of 12, the system is a multiple of the E. T., and of order zero.

In the illustration described under Th. iv. the notes of a multiple system (*kn*) are the same as those of system *n*, until the latter is complete. The rest of the representation consists simply of the same notes

Mr. R. H. M. Bosanquet on the

over again. To obtain the rest of the notes we should start from a new starting-point.

We may regard the system  $kn$  as consisting of  $k$  different systems, each having starting-points distant from each other by  $\frac{1}{k}$  of the interval of system  $n$ .

It is immediately evident that the system  $kn$  is of the  $k$ th order; for in system  $n$  there are  $k$  units of system  $kn$ ; and so in  $r$  units of system  $n$  there are  $kr$  units of system  $kn$ .

When  $n$  is not a prime, can be regarded as a multiple

of 59 is of the 7th order; 118 consequently a multiple of the 7th order, in which point of view it is of no interest; but, from the order, it may be also regarded as an independent system of the 2nd order, in which point of view it is of con-

*Major Thirds in Positive and Negative Systems.*

of the perfect third is  $-\cdot13686$ . Hence negative fifths (7 -  $\delta$ ) form their thirds in accordance with the theory of music. For if we take 4 negative fifths up, we have a negative departure ( $-4\delta$ ) which can approximately

Continuing the series to the right, each note of the next 12 fifths is affected with the mark / (mark of elevation), drawn upwards in the direction of writing. These notes join on to the unmarked duodene as follows :—

$$c-b-f\sharp-c\sharp-g\sharp\dots,$$

and so on.

Thus /c is 12 fifths to the right of c, and the interval /c-c is the departure of 12 fifths.

The next duodene to the right is affected with the mark //, which joins on to the last as before :—

$$/c-b-//f\sharp\dots,$$

and so on.

Proceeding in the same way, we have notes affected with such marks as ///, ////.

Return to the unmarked duodene, and let it be continued to the left; the notes in the next duodene on the left are affected with the mark \, (mark of depression), drawn downwards in the direction of writing. The junction with the unmarked duodene will be

$$\backslash c-\backslash g-\backslash d-\backslash a-\backslash e-\backslash b-f\sharp-c\sharp\dots$$

The next junction on the left will be

$$\backslash\backslash c-\backslash\backslash b-\backslash\backslash f\sharp\dots;$$

and, proceeding in the same way, we have such marks as \\\, \\\\.

Thus c-\e is a major third determined by eight fifths down in the whole series; and \e will have the departure (-8 $\flat$ ) from the E. T. note e derived from c.

*Notation applicable to all Regular Systems, Negative as well as Positive.*

As this notation simply consists of a determination of position in a continuous series of fifths, it may be applied to all regular systems, positive or negative; but, as it is not commonly needed for negative systems, it is not generally applied to them.

*Formation of Harmonic Sevenths in Positive and Negative Systems.*

The harmonic seventh is the interval whose ratio is 7:4. It affords a smooth combination, free from beats.

The departure of the harmonic seventh from the note which gives the E. T. minor seventh is -31174 (Rule I.).

Helmholtz observes that his system of just intonation affords an approxi-

Mr. R. H. M. Bosanquet on the

harmonic seventh. In fact, if we form a seventh by 14 positive systems ( $\text{fifth} = 7 + \delta$ ), we obtain a note with  $(-14\delta)$ , which can approximately represent the harmonic seventh.  $\delta$  represents such an interval.

observed (Roy. Soc. Proc. 1864) that the mean-tone negative, affords a good approximation to the harmonic seventh. If we form a seventh by 10 fifths up in negative systems we obtain a note with negative departure  $(-10\delta)$ , which represents the harmonic seventh.

*Tables of Regular and Regular Cyclical Systems.*

These tables permit us to calculate the departures and errors of various regular and regular cyclical systems. There is a quantity which may be also conveniently taken into account in these cases, viz. the departure of 12 fifths of the system. Putting  $\Delta = 12\delta$ .

The following Table of the characteristic quantities for the regular systems hitherto known.

The ordinary comma  $\left(\frac{81}{80}\right)$  is .21560. It is comparable to  $\Delta$ , and if introduced in its place in the Table would represent a non-cyclical system, lying between the system of 53

An illustration may be made as follows, which shows on inspection all the data involved in the above Table, and the properties of any other system introduced into it.

Take axes of abscissæ and ordinates, and set off on both distances representing tenths of E. T. semitones—for ordinary purposes 10 inches to the E. T. semitone answers best; for Lecture scale, 1 metre to the E. T. semitone.

On the axis of ordinates set off points representing the values in column Δ of the Table, and corresponding values for any other system required. Through each of these points rule a straight line parallel to the axis of abscissæ.

On the axis of abscissæ set off points representing the values  $-.19686$  and  $-.31174$ . Rule lines through these parallel to the axis of ordinates. These abscissæ represent respectively perfect thirds and perfect sevenths.

Draw lines inclined to the axis of abscissæ at angles  $\tan^{-1} \frac{3}{2}$  and  $\tan^{-1} \frac{6}{7}$ . These give, by their intersections with the lines of the different positive systems, the thirds and sevenths respectively.

Draw lines inclined to the axis of abscissæ at angles  $\tan^{-1} 3$  and  $\tan^{-1} \frac{6}{5}$ . These give, by their intersections with the lines of the different negative systems, the thirds and sevenths respectively.

The errors of the thirds and sevenths are the perpendicular distances of the intersections which determine them from the ordinates of perfect thirds and sevenths already constructed.

*In Regular Cyclical Systems, to find the number of Units in any Interval in the Scale.*

Let  $x$  be the number of units in the seven-fifths semitone, then

$$x \cdot \frac{12}{n} = 1 + 7\delta = 1 + 7\frac{r}{n},$$

or

$$x = \frac{n + 7r}{12}.$$

It is easy to see that  $x$  will always be integral if the order condition is satisfied (Th. iii.), viz. if  $7n + r$  is a multiple of 12.

For then  $7(7n + r) = 49n + 7r$ ; whence, casting out  $48n$ ,  $n + 7r$  is a multiple of 12.

We can now determine the remaining intervals in terms of  $x$  and  $r$ :—

Mr. R. H. M. Bosanquet on the

Interval.	No. of units.	
	Positive systems.	Negative systems.
tone .....	$x - r$	$x - r$
.....	$2x - 2r$	..
.....		
.....	$2x - r$	$2x - r$
.....		
.....	$3x - r$	$3x - 2r$
.....	$4x - 3r$	$4x - 2r$
.....	$5x - 3r$	$5x - 3r$
.....	$7x - 4r$	$7x - 4r$
.....	$9x - 6r$	$9x - 5r$
seventh .....	$10x - 7r$	$10x - 5r$
.....	$11x - 7r$	$11x - 6r$
.....	$12x - 7r$	$12x - 7r = n,$

negative systems are, of course, positive quantities.

*Employment of Positive Systems in Music.*

If we write down one of the duodenes of the notation,

$f\sharp - c\sharp - g\sharp - d\sharp - a\sharp - f - c - g - d - a - e - b,$

the positive systems form their thirds by 8 fifths down,

Such passages as this can be played on the harmonium hereafter described.

*Principle of Symmetrical Arrangement in Regular Systems.*

If we place the E. T. notes in the order of the scale, and set off the departures of the notes of any regular system at right angles to the E. T. line, sharp departures up and flat departures down, we obtain the positions of what may be called a symmetrical arrangement.

The distances of the E. T. notes from the starting-point are abscissæ, and the departures ordinates.

*Positive Systems.*

The subjoined is a symmetrical arrangement of the notes of General Thompson's enharmonic organ (p. 402). It is selected as not being too extensive for reproduction, as being of historical interest, and as illustrating the nature of the difficulty caused by the distribution of such systems into separate key-boards. Each of the single vertical steps represents the departure of one fifth.

The property of symmetrical arrangements, from which they derive their principal importance, is that, position being determined only by relations of interval, the notes of a combination forming given intervals present always the same form, whatever be the key or the actual notes employed.

Let us express, as before, the number of E. T. semitones, which is now our abscissa, by simple integers, and the number of departures of fifths, which is our ordinate, by a coefficient attached to  $\delta$ . Then we have only to note the values of the different intervals to obtain their coordinates with respect to any note taken as origin.

Thus the third is  $4-8\delta$ , or four steps to the right and eight down ( $c-\backslash e$ ); the fifth is  $7+\delta$ , seven steps to the right and one up ( $c-g$ ); the minor third is three to the right and nine up ( $\backslash e-g$ ); and so on.

Two notes are omitted from the otherwise complete series,  $b$  and  $\backslash\backslash d$ ; and we notice the number of otherwise complete chords which their absence destroys.

*Distribution over three Key-boards.*—As an example of the effect of this, we note that the notes of the chord of a minor are all present; but they are  $a_{1,2}-/c_1-e_2$ , so that the third and fifth are on different key-boards.

*Negative Systems.*

According to the enunciation of the principle of symmetrical arrangement, the positions should be taken lower for negative systems as we ascend in the series of fifths; but it is practically more convenient to use the positive form in negative systems as well. The coordinates of some intervals become different—the third is  $4+4\delta$ , the minor third  $3-3\delta$ , &c.

*Application of Principle of Symmetrical Arrangement to a "Generalized Key-board" for Regular Systems.*

A key-board has been constructed, on the principle of "symmetrical arrangement," in the following manner:—

The octave is taken = 6 inches horizontally (in ordinary key-boards the octave is  $6\frac{1}{2}$  inches). This is divided into 12 spaces, each  $\frac{1}{2}$  inch broad. These are called the 12 principal divisions of the octave. A horizontal line gives the positions of an E. T. series where it crosses them all.

The keys are then placed at vertical and horizontal distances from the E. T. line corresponding to their departures, on the supposition that the arrangement is positive.

The departure of 12 fifths up corresponds to a horizontal displacement of 3 inches from the player, and a vertical displacement of 1 inch up.

These displacements are divided equally among the fifths to which they may be regarded as due, i. e. the displacement of *g* with respect to *c* is  $\frac{1}{4}$  inch back and  $\frac{1}{12}$  inch up; so of *d* with respect to *g*, of *a* with respect to *d*, and so on.

Although only 3 inches of each key are thus exposed on a plan, yet the keys are all made to overhang  $\frac{1}{2}$  inch, and thus the tangible length of each key is  $3\frac{1}{2}$  inches.

The accompanying figure (p. 404) shows a small portion of the key-board, on a scale of half the real size.

The keys are each  $\frac{2}{3}$  inch broad, and their centres are  $\frac{1}{3}$  inch apart. There is thus  $\frac{1}{3}$  inch free between the adjacent surfaces of each pair of keys, and  $\frac{2}{3}$  inch altogether between the two keys which rise on each side of any given key. This is of importance; e. g., in the chord *c*-*e*-*g*-*c*, taken with the right hand, the first finger has to reach *e* between *d*-*f* and under the overhanging *c*.

The keys in the five principal divisions which have "accidental" names (e. g. *c*♯ or *d*♭) are black, the rest white.

There are seven keys in each principal division; the seven *c*'s are marked from *\\c* to *///c*, the unmarked *c* being in the middle. Thus there are 84 keys in each octave. The key-board controls an harmonium which contains the system of 53.

*Application of the Positive System of Perfect Thirds to the "Generalized Key-board" (Helmholtz's system, just intonation).*

If the thirds, such as *c*-*e*, are made perfect, and the fifths flat by .00244, a quantity which escapes the ear, we have the system here mentioned. Helmholtz makes a mistake in describing it ('Die Lehre von den Tonempfindungen,' ed. 3, p. 495); he supposes that the fifths are sharp instead of flat by the above interval; it is easy to see from the context that this is a mistake.

The notation of positive systems is applicable without specialization.

Mr. R. H. M. Bosanquet on the

of 53 is adopted. It is required to find rules of identification for passing from one principal division of the octave to another.

*Rule.*—In the system of 53 the notation of positive systems becomes subject to the following identifications:—

If two notes in adjoining principal divisions (e.g.  $c$  and  $c\sharp$ ) be so situated as to admit of identification (e.g. a high  $c$  and a low  $c\sharp$ ), they will be the same if the sum of the elevation- and depression-marks  $=4$ ; unless the lower of the two divisions is black (accidental), then the sum of the marks of identical notes  $=5$ .

This can only be proved by enumeration of a case in each pair of divisions. This enumeration is made in the writer's original paper. It is founded on the following principles:—

Noting that the 5-fifths semitone is 4 units (scheme following Th. i.), we see that  $c-c\sharp$  is 4 units, whence  $////c-c\sharp$ ,  $///c-\backslash c\sharp$ ,  $//c-\backslash c\sharp$  . . . . are identities; or, again,  $c\sharp-\backslash d$  is 4 units, and  $////c\sharp-\backslash d$ ,  $///c-\backslash d$  . . . . are identities.

*Application of the System of 53 to the "Generalized Key-board."*

An harmonium has been constructed which is arranged as follows:—

The note  $\backslash\backslash c$  is taken as the first note of the series, and receives the characteristic number 1. Then  $c$  is 4, and the remaining numbers can be assigned by the rules for the identifications in the system of 53 given above.

A number of notes at the top of the key-board are thus identical with corresponding notes in the adjacent principal divisions on the right at the bottom, e.g.  $//c=b=\backslash\backslash c\sharp$ . These permit the infinite freedom of modulation which is the characteristic of cyclical systems; for in moving upwards on the key-board we can, on arriving near the top, change the hands on to identical notes near the bottom, and so proceed further in the same direction, and *vice versa*.

It is to be noted that, in positive systems, displacement upwards or downwards on the key-board takes place most readily by modulation between related major and minor keys—not, as has been commonly assumed, only by modulation round the circles of fifths. In negative systems, on the contrary, displacements take place only by modulations of the latter type.

*Application of the System of 118 to the "Generalized Key-board."*

The 5-fifths semitone is here 9 units, and the 7-fifths semitone is 11 units. The major tone (2-fifths tone) is consequently 20, and the minor tone (10-fifths tone) is 18. Hence the notes in the successive principal divisions are alternately odd and even, and the identifications lie in alternate columns. These are not here further investigated, as no practical use has been made of the system.

Mr. R. H. M. Bosanquet on the

$c\sharp=12, d=21, \dots$

able to construct a key-board on the principles already  
ould give complete control over the notes of the system  
of such a key-board would be practically indistin-  
tuned to the positive system of perfect thirds, as  
rds of the system of 118 is too small to be perceived

*Negative System of Perfect Thirds (Mean-Tone System)  
to the "Generalized Key-board."*

ch as  $c-e$ , are made perfect, and the fifths  $\cdot 05376$  flat,  
one system. The forms of scales and chords in nega-  
different from those in positive systems. The scales are  
and the chords also. It is expected that this applica-  
practical importance.

scale of unmarked naturals on the plan, we can realize  
fingering. It is the same as that of the Pytha-  
he system of perfect fifths. The tones are all 2-fifths  
tones both 5-fifths semitones.

*of the Negative System of 31 to the "Generalized  
Key-board."*

little better than in the last case, viz.  $\cdot 05181$  flat; the

Now, when  $r=2$  we have the system of 118, which affords the closest approximation to what is required of any cyclical system known hitherto, the error of its third being  $\cdot00127$ .

Referring to Th. v., it is easy to see that no other even system of an order much below the 24th can afford a better approximation; for the number 118 differs from the value given by the above condition by little more than unity. Its multiple is always of the right order (Th. v.); there can therefore be no other system of the right order within 12 digits of the multiple either way, and the deviation of the value given by the condition cannot amount to 12 digits till near the 24th order; we therefore confine ourselves to systems of uneven orders.

Casting out 12's from 58·4526, we can take the remainder as 10·45, for the purposes of the search:—

$r$ .		$r \cdot 10 \cdot 45$ .		Remainder, casting out 12's.		Remainder re- quired for order $r$ (Th. iii.).
3	....	31·35	....	7·35	....	3
5	....	52·25	....	4·25	....	1
7	....	73·15	....	1·15	....	11
9	....	94·05	....	10·05	....	9
11	....	114·95	....	6·95	....	7

The coincidence at the 11th order is the closest so far; and it is easy to see, by considerations analogous to those above, that no subsequent system can afford another till a much higher order is reached.

For the 11th order, then, we have

$$11 \times 58 \cdot 4526 = 642 \cdot 9786;$$

and 643 is a system of the 11th order, as shown by its giving remainder 7 on dividing by 12 (Th. iii.).

Calculating the third of this system ( $\frac{8 \cdot 11}{633} = \text{dep.}$ ), and taking seven places, we have:—

$$\text{Departure of perfect third} = -\cdot1368629$$

$$\text{Departure of third of 643} = -\cdot1368585$$

$$\text{Error} = \cdot0000044 \text{ sharp.}$$

To five places both thirds are represented by  $-\cdot13686$ .

The intervals of this system will furnish us with simple numerical ratios, which represent with great accuracy the intervals of the perfect system.

We have (see the section on the number of units in any interval)—

$$7\text{-fifths semitone} = 60 \text{ units,}$$

$$5\text{-fifths semitone} = 49 \text{ units;}$$

### *Theory of the Division of the Octave.*

duce the remaining intervals. These values of the

"Experiments on the Brain of Monkeys.--No. I." By DAVID FERRIER, M.A., M.D., M.R.C.P., Professor of Forensic Medicine, King's College, London. Communicated by Dr. J. B. SANDESON, F.R.S.

The facts recorded in this paper are the results obtained by electrical stimulation of the brain of monkeys, after the method described by the author in the *West Riding Lunatic Asylum Medical Reports*, vol. iii. 1873. They formed part of a paper "On the Localization of Function in the Brain," read before the Royal Society on March 5, 1874\*. This memoir also contained the results of other experiments on the brain of monkeys, chiefly relating to the effects of localized lesions of several parts of the hemispheres, with a view to determine the significance, as regards sensation and motion, of the phenomena caused by electrical irritation. These experiments are not here recorded, but are reserved for comparison with the results of a more extended reinvestigation of a similar nature, on which the author has been for some time engaged, and which will shortly be laid before the Society.

In order to avoid unnecessary detail, and in order to place the results together for the purposes of comparison, the animals experimented on are described, the dates of experiment given, and numbers assigned to them, so that they may all be brought into relation with each other:—

Experiments on Monkeys (Macaques).

The circles marked on the woodcuts indicate the regions stimulation of which is followed by the same results. Several applications of the electrodes (which do not cover a larger diameter than a quarter of an inch) in or near the same region are necessary to mark off the area. To exactly define it is hardly possible, as the areas overlap each other, so that a complex set of movements may be caused by the conjoint stimula-

\* See *Proceedings*, vol. xii. p. 239.

r. D. Ferrier *on the Brain of Monkeys.*

centres which individually are capable of differentiation. They are very liable to occur if the currents are too strong. The woodcuts are therefore more or less indefinite as to their limits. Their centres indicate more precisely the points of stimulation.

In describing the results of stimulation by reference to the figures, the position of the electrodes, as far as possible, in relation to the individual convolutions, so that comparison may be made with the human brain.

The results are classified, and not related in the order in which they were obtained during the course of experiment.

Fig. 1.

Circle (1), figs. 1 & 2, corresponding to the postero-parietal lobule, or superior extremity of the ascending parietal convolution. The region is embraced between the parieto-occipital fissure and a short perpendicular sulcus at right angles to the median fissure.

**Results of stimulation :—**

- I. Not explored.
- II. The left foot is flexed on the leg, and the toes are spread out and extended.
- III. The right thigh is slightly flexed on the pelvis, the leg is extended, the foot flexed on the leg, and the toes are extended.  
This result was obtained by stimulation of the posterior margin of the circle. At other points the advance of the whole limb was not so distinct, but the flexion of the foot and extension of the toes was very marked.
- IV. The right leg is advanced, the foot flexed, and the toes extended.  
In this case some movements of the arm were also made, but not of a constant nature, and were therefore regarded as accidental complications.
- V. The right thigh is flexed on the pelvis, the leg extended, the foot flexed on the ankle, and the toes extended.
- VI. Flexion of the left thigh on the pelvis, extension of the leg, flexion of the foot on the ankle, extension and spreading out of the toes.
- VII. The right hind leg is advanced as in walking, the foot flexed on the ankle, and the toes extended.  
In this case slight adduction of the foot was observed on stimulation, just posterior to the lower end of the short perpendicular sulcus already referred to.
- VIII. Extension of the toes of the right foot, and flexion of the foot on the ankle.  
In this case also a tendency to adduction of the leg and foot was observed.
- IX. Flexion of left thigh on pelvis, extension of the toes, and flexion of the foot. (One observation only.)
- X. Not explored.
- XI. Extension of the toes of the right foot, and flexion of the foot on the ankle.
- XII. Not explored.
- XIII. Not explored.

The general result of stimulation of this region is to show that it is a centre for the movements of the hind leg, and apparently those concerned in walking.

#### D. Ferrier on the Brain of Monkeys.

ed that in some cases the movement is only partially  
is frequently the case, and, as will be seen in the sub-  
movement, at first of limited extent, gradually merges  
x one, involving numerous muscles.

1 & 2. This embraces the upper extremity of the  
convolution, and also stretches across the fissure of  
include the anterior division of the upper extremity of  
etal convolution.

ed.

d.

semiflexed condition, and pointing to the middle line of the body.

The combination of actions is just such as when a monkey scratches its abdomen with its hind leg.

The muscles of the trunk participated in the movements, so that the body was twisted to the opposite side.

- III. The action in this case was in all respects similar to that recorded in II.
- IV. In this case epileptic or choreic convulsions, which readily occurred on the slightest stimulation, rendered analysis of the movements impossible.
- V. In this case the action described in II. was very distinct, viz. the rotation outwards of the thigh, the rotation inwards of the leg and foot, and the grasping portion of the toes pointing towards the middle line.
- VI. As in I. and V., the thigh on the opposite side (left) was flexed and rotated outwards, the leg and foot inwards, while the toes were spread out.
- VII. In this case also the movements were very distinct, consisting in rapid combined muscular action, bringing the foot and toes inward as if to scratch the body.
- VIII. The results in all respects the same as VII.
- IX. Similar action, viz. rotation outwards of the thigh, inwards of the leg, and the foot brought up with a sort of grasping movement of the toes to the middle line of the trunk.
- X. Not explored.
- XI. Action in all respects as described in IX.
- XII. Not explored.
- XIII. Not explored.

Circle (3), figs. 1 & 2, corresponding to the situation of a parallel sulcus in the upper part of the ascending frontal convolution.

It may be taken as included in the previous one, but is marked separately on account of being also a centre for the tail.

Results of stimulation :—

- I. Twisting of the trunk to the left, along with some not well-defined movements of the right leg and tail.
- II. In this case the same action was observed as resulting from stimulation of circle (2), viz. flexion of thigh, rotation outwards, leg and foot rotated inwards, with the toes stretched out, semiflexed towards the middle line of the body. Movement of the tail was not noted.
- III. Similar action. Tail not noted.

D. Ferrier on the Brain of Monkeys.

ed.

on of the leg, but at the same time the right arm

results described under VII.

red.

ored.

ult of these observations, all agreeing with each other

ts, is to show that circle (2) is a centre for the hind

character from circle (1), being more concerned in

and leg as an organ of prehension or climbing, instead

of simple progression. The subdivision circle (3)

Here it must be noted that the centres which cause the above-described movements of the hind leg, as well as those afterwards to be described which cause clenching of the fist, had been under stimulation previous to the exploration of this region. Hence the result is to be looked upon as the combined action of all three centres. This is the real difficulty experienced in analysis of the complex movements of the limbs, there being always a tendency to have complications arising from the irritable condition which continues in the regions which have been under experimentation. This, along with the tendency to convulsive spasms of a choreic or epileptiform nature, lasting for minutes after the cessation of stimulation, renders it frequently excessively difficult to draw accurate conclusions. The results described have always been those arrived at after as complete exclusion as possible of these adverse conditions.

- VI. Retraction and straightening out of the left arm, as already described.
- VII. Noted as action of the latissimus dorsi, this being regarded as the chief cause of the movement.
- VIII. In this case the shoulder was first elevated, the humerus adducted, the wrist and hand fully extended, and the whole arm straightened and drawn backward in the manner already described in II.
- IX. Left arm adducted, and then extended and retracted.
- X. A similar result.
- XI. Not explored.
- XII. Not explored.
- XIII. Action of the latissimus dorsi as already described. The condition of the hand is not noted.

The results of stimulation, therefore, of this region agree with each other.

I have observed frequently that only very partial action was occasionally obtained at some points in this circle; sometimes only an appearance of adduction of the arm. The complete action, however, appears to be such as I have described as resulting from stimulation of the centre of this circle.

Circle (5), figs. 1 & 2, corresponding to the posterior third of the superior frontal convolution.

- I. The results in this case were not very definite. They consisted in a complication of the movements of the leg, already described as resulting from circle (2), along with an extension forwards of the right arm.

D. Ferrier on the Brain of Monkeys.

extension forwards of the left arm and also of the leg.  
be noted that the leg-centres had been already under  
previous to exploration of this centre.  
forwards of the right arm and hand.

were not very definite, as the animal was continually  
own into convulsive spasms on application of the elec-

on and hand are extended forwards, as if to touch or  
thing in front.

e result, but apparently resembling IX.

plication due to conjoint irritation of the leg-centres,  
e a centre for a definite forward extension of the arm.

tal convolution (a), (b), (c), (d), figs. 1 & 2.

the letters a, b, c, and d, indicating circles extending

Continued in a choreic manner after stimulation.

- c. Same result as *d*.
- b. Extension of the fingers, but more especially of the thumb.
- a. Thumb only is extended.

Spasmodic jerking of the thumb continued several seconds after withdrawal of the electrodes.

- III. a. Clenching of the fist. The movement began with the thumb, which was first adducted.

b. As before, clenching of the fist; at the same time the extensors of the wrist and fingers were seen to be contracted.

c. Momentary application of the electrodes caused adduction of the thumb, followed on longer stimulation by clenching of the whole fist and slight pronation of the hand.

After several other regions had been explored, these points were again stimulated in succession.

The second result at point *d* was extension of the thumb and fingers instead of flexion.

A second stimulation of point *b* caused, first, adduction of all the fingers, then extension of the wrist and flexion of the distal phalanges, the proximal phalanges not being flexed till the wrist was fully extended.

The repeated application of the electrodes was followed in this animal by an epileptiform fit, affecting both sides of the body and lasting for three minutes.

- IV. a. Abduction of the thumb.

At the same time the right angle of the mouth was retracted, owing, as will be seen, to the proximity of the centre for the platysma.

b. At first extension of the thumb, then, on longer irritation, extension of the wrist and flexion of the fingers.

c. Thumb adducted, and then firm clenching of the fist.

d. Clenching of the fist and pronation of the hand.

- V. a. One application of the electrodes caused extension of the thumb; another caused adduction of the thumb and clenching of the fist, with extension of the wrist.

b. Clenching of the fist and extension of the wrist, as before.

c. Clenching of the fist as before, with complete pronation of the hand.

d. Clenching of the fist repeated, but complicated with the action of the latissimus dorsi and backward extension of the arm.

The reason of this is the proximity of the point *d* to circle (4).

- VI. a, b, c, d. A similar result in all, viz. flexion of the fingers and extension of the carpus.

c. First adduction and flexion of the thumb of the fist and pronation of the arm.

IX. *a, b, c, d.* Slight touch causes adduction of the longer stimulation by flexion of the fingers and of the fist.

Stimulation close to the fissure of Roland movements, and also very decided extension of fist was completely closed.

X. Not explored.

XI. Results essentially similar to IX.

XII. Not explored.

XIII. Clenching of the fist as in former experiments

The variations described in the movements resulting of the ascending parietal convolution are apparently all different aspects of combined muscular contractions, which serve to cause closure of the fist or the grasp of the hand. Centres for the extensors and flexors, or for the extensors, of the individual digits could not be definitely

Owing to the proximity of the centre for the platysma at the lower end of the ascending parietal, very frequent firm closure of the fist, there was decided retraction of mouth on the same side.

Ascending frontal convolution :—

Circle (6), figs. 1 & 2. The position of this is on posterior extremity of the ———

This action of the mouth will be explained by reference to the action of the centre immediately below it.

- II. Supination and flexion of the forearm and hand.
- III. A similar result.
- IV. Flexion of the forearm, clenching and supination of the hand.
- V. Shoulder raised, forearm firmly flexed, hand clenched and supinated. The hand ultimately raised to the mouth, the angle of which is retracted and elevated.
- VI. Flexion, with slight supination, of the forearm and hand.
- VII. Flexion and supination of the right forearm and hand, accompanied with clenching of the fist when the stimulation was applied near the fissure of Rolando.
- VIII. Apparent action of the biceps as before.
- IX. Flexion and supination of the forearm and hand.

In this case it was found very decidedly that stimulation close to the fissure-of-Rolando side of the convolution caused the action of the biceps to be associated with clenching of the fist. Towards the lower margin of the circle the same movements were associated with retraction of the angle of the mouth.

- X. Not explored.
- XI. Same results as IX. exactly.
- XII. Not explored.
- XIII. Results as in other cases, viz. flexion and supination of forearm and hand, with clenching of the fist.

These uniform results point very clearly to this as the centre for the biceps and muscles concerned in bringing the hand up to the mouth.

Circle (7), figs. 1 & 2. Still in the ascending frontal convolution, in position immediately below the centre for the biceps.

- I. Retraction and elevation of the right angle of the mouth.
- II. Retraction (with elevation) of left angle of the mouth. Occasionally in stimulation the action was conjoined with that of the biceps.
- III. Not explored.
- IV. Not explored.
- V. Spasm of the right angle of the mouth and of the cheek-pouch.
- VI. Not explored.
- VII. Elevation of right angle of mouth.
- VIII. Same result as VII.
- IX. Angle of the mouth raised and retracted, along with action of the biceps and flexors of the fingers.
- X. A similar result. In this case, after several other parts had been under exploration, excitation of this region gave rise to a species

These results indicate that this is a centre of the angle of the mouth, and apparently of the

Circle (8), figs. 1 & 2. Lower down in convolution.

- I. The action is similar to that resulting from centre, but seems especially to cause elevation of the nose on the right side.
- II. At the anterior part of the circle the lip is drawn upwards and backwards (zygomatic lower margin of the circle the action is that of the depressor anguli oris, so as to expose the teeth).
- III. Not explored.
- IV. Not explored.
- V. Elevation of the upper lip (right side) and stimulation was followed by prolongation of the right angle of the mouth and ala.
- VI. Not explored.
- VII. Elevation of right side of upper lip and depression of the lower lip.
- VIII. Combined action of the elevator of the nose and of the depressor anguli oris, so as to expose the teeth.
- IX. Elevation of the upper lip and depression of the lower lip and exposure of the teeth.

quently exhibited by monkeys under the influence of fear or anger, viz. the exposure of the canine teeth.

Circles (9) and (10), fig. 2, corresponding in situation to the lower part of the ascending frontal convolution, or posterior part of the inferior frontal convolution, above the lower end of the fissure of Sylvius (Broca's convolution).

I. (9). The lips pout, mouth gradually opens, and the tongue is protruded.

(10). Action similar as to the mouth, but the tongue is retracted. Longer stimulation caused movements of the mouth and tongue, as in mastication.

II. (9). Mouth opened and tongue protruded.

(10). Tongue retracted.

Movements of mastication made by continued stimulation.

III. Same results as in I. and II.

IV. Not explored.

V. (9), as in former cases, causes opening of the mouth and protrusion of the tongue.

(10) causes retraction of the tongue.

Movements of mastication also caused on longer stimulation.

VI. Not explored.

VII. (9). Mouth opened and tongue protruded.

(10). Same result, but tongue apparently retracted.

VIII. (9). Opening of the mouth and protrusion of the tongue.

(10). Same result, with retraction of the tongue, followed on continuous stimulation with opening and shutting of the mouth, and alternate protrusion and retraction of the tongue.

IX. Similar results to VIII.

X. Not explored.

XI. Results of VIII. confirmed.

XII. Not explored.

XIII. Movements of the mouth and tongue, but not of any very definite character, the animal being in a state of exhaustion, and the excitability of the brain very weak.

*D. Ferrier on the Brain of Monkeys.*

point very definitely to a centre for the movements of tongue, the muscles concerned in mastication and also in position is significant, as being the homologue in man which is the seat of lesion in the disease known as aphasia, posterior extremity of the lower frontal convolution. Lesion is generally on the left side, but the bilateral movement by the experiments to be induced from both right and

figs. 1 & 2, corresponding to the lower termination of frontal convolution and region of the inferior termination of frontal sulcus (the conjoint extremities of the ascending angular gyrus).

of the right angle of the mouth, apparently the platysma to action.

Effect was kept up after stimulation in a spasmodic manner.

Angle of the mouth retracted. The head becomes drawn up by powerful contraction of the platysma.

Fig. 1

**XIII.** Strong contraction of the platysma, and retraction of the left angle of the mouth.

The results of stimulation of this centre agree with each other, and indicate a centre for the platysma. The frequent retraction of the angle of the mouth observed on causing clenching of the fist is explained by the proximity of the two centres to each other.

**Island of Reil (central lobe), within fissure of Sylvius :—**

Owing to the central lobe in the monkey being completely concealed within the lips of the fissure of Sylvius, mechanical injury and considerable hæmorrhage is necessarily caused in the attempt to expose it clearly. This is mentioned as a possible explanation of the negative results, but it is not sufficient to account for the apparent non-excitability of this region.

The island was exposed and experimented on in monkeys IX. and XIII.

**IX.** Electrization of the island of Reil gave no results.

Some movements of the mouth were caused during the introduction of the electrodes within the fissure, but were referred to stimulation of the mouth-centres in close proximity.

**XIII.** The result in this case was also negative.

To test this matter more fully, another monkey, not among those already numbered, was experimented on on December 10.

The lips of the fissure of Sylvius were carefully separated, without causing much injury or hæmorrhage. After the hæmorrhage had entirely ceased, the electrodes were applied directly to the surface of the central lobe.

No effect was observed.

After the animal had been allowed to rest for some time, it was then tested as to the excitability of the other centres. The hand, leg, and mouth could as usual be acted on by stimulation of their respective centres.

The electrodes, insulated up to the point, were again applied to the island of Reil.

No result was observed.

Stronger and continuous stimulation gave rise to choreic spasms of the angle of the mouth. This was attributed to diffusion of the current, owing to its being strengthened, and irritation of the proximate centres for the angle of the mouth.

Another application of the electrodes within the lower end of the fissure caused movements of the mouth and tongue. These also may have been due to conduction to the mouth-centres already described.

Beyond these, stimulation of the island of Reil yields negative results.

r. D. Ferrier on the *Brain of Monkeys*.

figs. 1 & 2, including the superior and middle frontal convolution, the antero-parietal sulcus (Huxley), sulcus præcentralis and the anterior extremity of the supero-frontal sulcus.

The stimulation of these convolutions were always so universal that the general result of experimentation in ten monkeys may be taken as the result.

The results were :—

1. Elevation of the eyebrows and the upper eyelids, turning of the eyes to the opposite side, and great dilatation of both pupile.

2. In stimulation of the centre for the forward extension of the arms, movement of the eyes and head was called into play.

3. The orbital convolution (including all in advance of the sulcus

above) gave no results.

4. The region (including all in advance of the anterior extremity of the frontal sulcus, and indicated sometimes by a slight sulcus between the median fissure) and orbital convolution.

5. The above were subjected to stimulation in four cases, viz. I., V.,

6. The results could be observed, either from the antero-frontal or orbital

III. Eyes directed upwards.

IV. Not explored.

V. Not explored.

VI. Not explored.

VII. Both eyes are directed to the right (whether there was any upward direction was not noted).

The pupils became contracted.

VIII. The eyes were directed to the right (notes do not mention as to whether any upward direction was observed). The pupil was thought to be slightly contracted. The eyelids during the stimulation had a tendency to close. The head also inclined to the right side.

IX. Both eyes directed upwards and to the left. Pupils contracted?

In this animal, which was allowed to remain quite conscious during stimulation, an experiment was made as to vision by holding before it a teaspoonful of milk, which it was eager to seize. In its attempt this point was stimulated, with the effect of causing confusion of vision and some difficulty in reaching the milk.

X. Both eyes turned to the left and slightly upwards. The pupils contract and the eyelids tend to close.

XI. Both eyes to the right and upwards. Pupils not observed.

XII. Both eyes to the left and upwards.

XIII. Both eyes to the left and upwards. The pupils contract.

Descending limb, circle (13').

I. Eyes to the right and downwards. Head is inclined to the right side.

II., IV., V., VI. Not explored.

III. Eyes to the right and downwards.

VII. Both eyes directed to the right. Pupils contract.

VIII. Eyes down and to the right. Eyelids tend to close. Head directed slightly to the right side.

IX. Eyes directed down and to the left.

X. Eyes to the left and slightly downwards. The eyes half closed. Pupils contract.

XI. Eyes to the right and downwards. Pupils not observed.

XII. Same as XI.

XIII. Both eyes directed downwards and to the left. The pupils contracted.

These results are obtained on the *pli courbe* from the centre for the platysma (circle (11)) down to the termination of the descending limb in the *pli de passage* connecting it with the occipital lobe.

Experiments will be given subsequently as to the effects of destruction

r. D. Ferrier *on the Brain of Monkeys.*

and an attempt made to interpret the signification of these eyeballs.

oro-sphenoidal convolution, circles (14), fig. 2 (extending thirds of its length from above downwards).

ion of right ear, head to the right, eyelids opened widely, ted to the right with great dilatation of the pupils.

n of left ear, eyes opened widely, head quickly turned to Pupils not observed.

of left ear, head and eyes turned to the left, and dilatation of pupils.

of the mouth, with some movements of the cheek-pouches and tongue, were observed.

X. In this case stimulation of the corresponding region caused some indistinct movements of the mouth and lips.

XIII. In this case there were some movements of the jaws; not of any decided character.

These are all the facts I have been able to gather from experimentation on this region, which is attended with some difficulty.

Fig. 3.

Lower temporo-sphenoidal convolution (inner aspect) and region of the uncinate convolution and occipito-temporal gyrus. Circle (15), figs. 2 & 3.

This region was reached and stimulated in the following cases with these results:—

VIII. Spasmodic contraction of the left lip and ala of the nose. The result was a sort of torsion or closure of the nostril, as when an irritant is applied to it. The action was on the same side, not crossed, as usual.

IX. Spasmodic torsion of the right lip and nostril, also on same side as stimulation.

X. Similar results, viz. an elevation of the right nostril and lip, so as to cause partial closure. In this case the phenomenon was observed on both sides, the right more especially, however.

XIII. Torsion of the right lip and nostril, as before.

In all these cases the phenomena were exactly alike. The fact of

r. D. Ferrier on the Brain of Monkeys.

the same side as the stimulation, is explained by the origin of the tract from the *subiculum cornu ammonis*, and which passes through the olfactory bulb without decussation.

These results mainly indicate a perception or subjective sensation of smell, and point to this as the central seat of the sense of smell.

(superior and middle convolutions).

Experimented on in I., III., V., VII., VIII., IX., X., XI., and in another, not numbered, on November 21.

Except in the case of X., to be afterwards mentioned, the results were negative as far as outward phenomena were concerned.

These results are not to be attributed to exhaustion of the brain, for the other centres at the same time gave the

In X. it was observed that stimulation of the inferior occipital lobe towards its inner aspect caused uneasy movements in the body and tail, the head being turned to the left (opposite side).

Occasionally also a plaintive cry, as if from annoyance, was heard. On cessation of the irritation the animal subsided into its

The result may be attributed to conduction of the current to some other part of the dura mater; but, owing to the diffi-

Results :—

VIII. Left corpus striatum.

Stimulation caused bending of the body to the right (pleurosthotonus) and rigidity of the limbs in the position of flexion.

XIII. Right corpus striatum.

Curving of the head and trunk to the left, the platysma being strongly in action, while the limbs were maintained in a rigid condition in the position of flexion.

The results indicated that all the muscles were simultaneously in action, individually stimulated by irritation of the cortical centres.

Optic thalamus.

Stimulated in VIII. and XIII. Results :—

IX. Entirely negative.

XIII. Also negative after several explorations of the upper surface.

Application of the electrodes to the inner aspect in the region of the soft commissure caused a spasmodic extension of the limbs. There was no cry of pain. The result was not constant, and it may therefore have been an accidental complication.

No other experiments were made on these ganglia in the monkey, on account of their resemblance to the results obtained on other animals.

Corpora quadrigemina.

These ganglia were subjected to experimentation in the following seven cases, viz. V., VI., VIII., IX., X., XII., XIII., with the results :—

V. In this case the exploration was not sufficiently definite, as the exact position of the electrodes was not observed, and death occurred before a more careful exploration could be made.

The application of the electrodes to the ganglia on the left side (position as to the testes or nates not ascertained) caused the animal to utter various barking, howling, or screaming sounds of an incongruous character.

The head was drawn back and to the right, and the right angle of the mouth was strongly retracted while the stimulation was kept up. The tail was raised and the limbs were thrown into contortions, but nothing further was ascertained, as the animal died from hæmorrhage.

VI. In this case irritation of the right anterior tubercle (nates) caused intense dilatation of both pupils (especially beginning in the left), elevation of the eyebrows, and turning of the eyeballs upwards and to the left, at the same time that the head was turned in the same direction with an intensely pathetic expression.

Momentary application of the electrodes to the posterior tubercles (testes) caused the animal to bark loudly, the sound passing with longer stimulation into every conceivable variation of howling and screaming.

r. D. Ferrier *on the Brain of Monkeys.*

uous application of the electrodes for several seconds ultimately firm clenching of the jaws, retraction of the mouth (particularly the left), elevation of the eyes and retraction of the ears. The pupils were dilated, eyes open, and the head thrown back. The tail became elevated, the limbs, after contortions of various kinds, became rigidly back, the arms drawn back and flexed at the elbows and approximated to the sides. A complete state of opisthotonus induced. The dilatation of the pupils occurred on both nates and testes; the screaming &c. only on the testes.

Results in this case were essentially the same as in VI., as the dilatation of the pupils, howling, and rigidity of the

stimulation of the anterior tubercle on the right side elevation of the eyebrows, dilatation of the pupils, and turning of the eyes to the left. Irritation of the ganglia for a moment caused a condition of opisthotonus, and the phenomena under VI.

Stimulation of the testes caused utterance of every variety of howling, ultimately trismus and general opisthotonus. In IX.

May 13, 1875.

Dr. J. BURDON SANDERSON, Vice-President, in the Chair.

The Presents received were laid on the table, and thanks ordered for them.

In pursuance of the Statutes, the names of the Candidates recommended for election into the Society were read from the Chair as follows:—

William Archer, M.R.I.A.  
James Risdon Bennett, M.D.  
Dietrich Brandis, Ph.D., F.L.S.  
James Caird, C.B.  
Prof. John Casey, LL.D.  
August Dupré, Ph.D., F.C.S.  
James Geikie, F.R.S.E.  
James Whitbread Lee Glaisher,  
M.A.

John Baboneau Nickterlien Hennessey, F.R.A.S.  
Emanuel Klein, M.D.  
E. Ray Lankester, M.A.  
George Strong Nares, Capt. R.N.  
Robert Stirling Newall, F.R.A.S.  
William Chandler Roberts, F.C.S.  
Major-General Henry Y. D. Scott,  
R.E., C.B.

THE CROONIAN LECTURE, "Experiments on the Brain of Monkeys" (Second Series), was delivered by DAVID FERRIER, M.A., M.D., Professor of Forensic Medicine, King's College. Communicated by Dr. SANDERSON, V.P.R.S. Received April 27, 1875. The following is an Abstract:—

This paper contains the details of experiments on the brain of monkeys, supplementary to those already laid before the Society by the author. They relate chiefly to the effects of destruction, by means of the cautery, of localized regions previously explored by electrical stimulation.

Twenty-five experiments are recorded in detail, and the individual experiments are illustrated by appropriate drawings. The results are briefly summed up as follows:—

1. Ablation of the frontal regions, which give no reaction to electrical stimulation, is without effect on the powers of sensation or voluntary motion, but causes marked impairment of intelligence and of the faculty of attentive observation.

2. Destruction of the grey matter of the convolutions bounding the fissure of Rolando causes paralysis of voluntary motion on the opposite side of the body; while lesions circumscribed to special areas in these convolutions, previously localized by the author, cause paralysis of voluntary motion, limited to the muscular actions excited by electrical stimulation of the same parts.

D. Ferrier on the Brain of Monkeys. [May 27,

of the angular gyrus (*pli courbe*) causes blindness of the other senses and voluntary motion remaining unaffected. Blindness is only of temporary duration, provided the other hemisphere remains intact. When both hemispheres are destroyed the loss of visual perception is total and permanent.

of electrical stimulation, and the results of destruction of the temporo-sphenoidal convolutions, indicate that they are the seat of the sense of hearing. (The action is crossed.)

of the hippocampus major and hippocampal convolutions produces the sense of touch on the opposite side of the body.

of smell (for each nostril) has its centre in the subiculum, or tip of the uncinate convolution on the same side.

of taste is localized in a region in close proximity to the olfactory bulb and is abolished by destructive lesion of the lower part of the sphenoidal lobe. (The action is crossed.)

of the optic thalamus causes complete anæsthesia of the body.

of the occipital lobes produces no effect on the special powers of voluntary motion, but is followed by a state of refusal of food, not to be accounted for by mere constipation consequent on the operation. The function of the occipital lobes is regarded as still obscure, but considered to be in some

I. "On the Liqutation of Alloys of Silver and Copper." In a Letter addressed to the Secretaries of the Royal Society, by Col. J. T. SMITH, Madras Engineers, F.R.S. Received April 2, 1875.

It has occurred to me that it might be useful, as a guide to future inquiries, if I were to communicate, in reference to Mr. Roberts's paper "On the Liqutation, Fusibility, and Density of certain Alloys of Silver and Copper," the results of some experiments made by me many years ago, the conclusion to which I was led being that the separation of the constituent parts of an alloy containing  $91\frac{1}{2}$  per cent. of silver was not so much due to the rapidity or slowness with which the heat of the fluid metal was abstracted, as to the inequality affecting its removal from the different parts of the melted mass in the act of consolidation. Thus, if a crucible full of the melted alloy were lifted out of the furnace and placed on the floor to cool, the surface of the melted metal within it being well covered with a thick layer of hot ashes, the lower parts of the mass, after it had become solid, would be found to contain less silver in proportion than the upper surface.

If, on the other hand, the crucible were left to cool while imbedded in the furnace, the upper surface only being exposed to the air, except a thin layer to protect it from oxidation, then the lower parts would, after solidification, be found finer than the upper surface.

The variations here referred to are not considerable; but they sometimes become of practical importance, especially in those cases wherein, as the practice of the Indian Mints used to be, the value of a large mass of coins is calculated by the assay of samples cut from a representative bar, formed by melting together a number of the pieces selected from the mass.

Under certain conditions, different parts of a bar of 50 or 60 lbs. weight, cast horizontally, though composed of metal which, previous to being poured from the crucible, was perfectly homogeneous, might be found to vary as much as  $1\frac{1}{2}$  or even 2 per cent. A much smaller difference than this might be the cause of considerable loss or gain in the valuation of a large invoice.

This peculiar action in the cooling of melted silver alloy first attracted notice by observation of the fact that coinage-ingots, which were about 15 inches high,  $2\frac{1}{2}$  inches broad, and  $\frac{5}{8}$  inch thick, cast in vertical iron moulds, were *uniformly* finer at their upper surface and coarser at their sides and bottom, especially at the corners.

It was at first thought possible that this might be due to the combustion of the oil employed to lubricate the moulds causing a sensible refinement of the metal, as the flames were frequently tinged by copper; but the same increased fineness of the tops of the ingots was found to exist when they had been poured into new iron moulds which had never

and also when burnt clay-moulds were used—the only phenomenon did not occur being when clay-moulds were used, and the melted metal, instead of being at the top, was caused to rise from the bottom upwards.

And that, by using artificial means to cool the ingots from the face only, the usual refinement was prevented, and the metal caused to become as inferior in quality at the top as, in the reverse, it would have been at the bottom.

For many experiments, it was satisfactorily established that, for the form the metal might take, the act of cooling caused a migration of the copper towards the surfaces from which the heat was removed, those parts of a bar or ingot being the finest which con-

tents here referred to were part of a series constituting a study of all the ordinary processes of a mint, with the view of ascertaining the unavoidable causes of the loss of precious metal, if any, and of increasing their amount. In the course of the series more experiments were made of standard silver under various conditions; and as a demonstration of the fact that, with the exception of a considerable proportion left in the sweepings, which might be used for silver coinage, to less than the twenty thousandth part, no loss ought to occur; and hence that, if the quantity left in

of 1 dwt. in the pound, or the  $\frac{1}{20}$  part; and as the coins were cut in a double row down each strap, from top to bottom, it followed that every coin at one end of a transverse diameter touched the edge of the strap, or the coarser metal, and at the other end of the same diameter touched the interior or finer metal.

Thus the different parts of coins composed of standard silver vary essentially in fineness at different points of their circumference. If we were to call those parts of the coins north and south which, before they were cut, lay in the direction of the length of the strap, and those at right angles thereto east and west, it would give a correct idea of this peculiarity to say that there is no essential difference between the north and south sides of the piece, but a considerable one between the east and west, frequently amounting to  $\frac{3}{4}$  dwt. in the lb., and in coins cut from certain portions of each strap to more than 1 dwt., or  $\frac{1}{20}$ , sometimes even to 2 dwts. From this circumstance it is evident that assays taken in the manner formerly used for the pyx examination of coins in some of the Indian Mints, by flattening one edge of a coin and cutting off a part of it for trial, may often lead to its unjust condemnation; and when the whole work of a mint of many thousands of pounds value is liable to rejection in consequence of an unfavourable report upon individual coins, which more than once occurred in Madras, it is obvious that a more correct method of ascertaining the average fineness of the whole outturn is very desirable.

For this purpose it was suggested that the samples for assay should be taken from the centre of each coin, or by a ring representing the whole circumference. But the true average fineness of the whole of a large silver coinage is much more easily and better arrived at by taking out a large number of the coins indiscriminately, and having melted them together into a perfectly uniform and homogeneous compound, proceed according to the following method, which was latterly adopted in India.

While the representative coins are undergoing fusion, a portion is taken out in its fluid homogeneous condition and granulated by pouring into cold water. A number of the granules are then selected for assay, and after being carefully dried and weighed, are wholly (that is, each granule in its integral state) dissolved in acid. The silver contained in them is afterwards separated as a chloride, and estimated in the usual way, the fineness of the mass being calculated by a comparison of the weight of pure silver thus ascertained with the original weight of the granules.

When carefully prepared, as above described, there is a near agreement in the finenesses of the single granules, which rarely differ from the mean fineness of the metal so much as two thousandths when individually assayed, more than half of them being found within one thousandth, and the average of a number consequently very close to the truth.

r. C. H. Jones on *Reversed Tracings*. [May 27,

*Reversed Tracings*." By C. HANDFIELD JONES,  
antab., F.R.S. Received March 22, 1875.

began to use the sphygmograph I was advised by a  
spring (which only gave a pressure up to 200 grammes)  
which was capable of giving 400. While working with  
obtained from the pulse of a healthy man, æt. 52, the  
fig. I., the pressure employed being 384 grammes. It  
an ordinary tracing of a normal pulse, except that it is  
glass is turned round and viewed from the non-smoked  
is all *en règle*; but viewed from the side on which it was  
y-turvy sideways, if such a phrase be permissible. I  
hend it, and showed it to a friend more versed in  
than I was then; but he could only say that I must have  
ge mistake. Other good observers thought the tracings  
ary," but could give no explanation of their *raison*  
ng how I could have erred, I varnished my slide and put  
that I might get to understand it some day. I noted,  
t that the pressure was very high, viz. 384 grammes.  
sually employ for average pulses is 84 grammes to 140.  
ake observations, I noticed occasionally that the lever,  
aved in an unusual manner; instead of jerking up-  
onwards, while the elevation was gradual, and this

Fig. I. Reversed tracings taken from pulse of a healthy male, set. 52. Pressure employed 384 grammes. 1871.

II. Tracings from pulse of a man, set. about 25. Pressure employed for *a*, *b*, and *c* 140 grammes, for *d* 84 grammes. *a* is normal, *b* and *c* are reversed; *d*, taken two or three minutes later, is normal again.

III. Tracings of pulse of Mr. H., set. about 35, healthy and robust. *a*, normal, with pressure 300 grammes; *b*, reversed, with pressure 750 grammes.

IV. Shows effect of increased pressure in lowering rise. Pulse of male, set. 19, epileptic. *a* taken with pressure 56 grammes, *b* with 84 grammes, *c* with 112 grammes, *d* with 196 grammes.

V. Tracings taken with schema. *a*, spring resting on artery, pressure 2 oz., lever jerking upwards; *b*, plate resting on artery, pressure 30 oz., lever jerking downwards.

ified in fig. IV.; it may even reduce the tracing to a point beyond this it seems as if the force of pressure "could no longer be increased in any intelligible way, after a sufficient force has been used to compress the artery, a greater amount of force should produce a fall of the tracing.

Considering these tracings it seemed very important to determine whether the rise really corresponded to the rise of the normal pulse. The constant presence of the notch in the apparent pulse suggested that this was perhaps not systolic in cardiac time; and on examination this proved to be the case; for when the sphygmograph applied to Mr. Hawksley's radial was giving a normal tracing, at a rate below 70 per minute, I observed, on the other radial, that each *drop* of the lever coincided exactly with the pulse, and was therefore systolic in time, so that, of course, the notch must have been diasystolic. This conclusion was substantiated by observations made with a "schema," every contraction of the ball causing a fall of the lever under circumstances to be mentioned. The "schema" employed was rather a rude modification of Robinson's syringe, with a long flexible tube attached, the end of which was obstructed to make the pressure more effectual. The tube was placed under the *spring* of the sphygmograph, so that when the ball jerked the lever up, and produced such a tracing as is shown in fig. V., but when the tube was shifted a

appears to be so closely connected with the existence of an undue amount of pressure. In fig. II. I find it rather difficult to think that the degree of pressure did not in some way modify the form of the tracing. Of course if, as is most probable, reversal of the tracing depends solely on the cause I have pointed out, and can be produced in no other way, no possible effect can be attributed to any alteration of the spring-pressure, as the spring is dissociated from the cause of motion.

The only notice I have found in Marey's work of any thing like such traces as I have described occurs at p. 282, where he says :—"Type 84 presents a singular peculiarity, the rebound has not had time to finish before the arrival of a fresh pulsation ; the result is a form which might be taken for a tracing inverted (*écrit en sens inverse*) ; but this depends only on the phenomena of dicrotism not having had time to work themselves out (*s'accomplir*) between two successive pulsations."

The circumstance that the aortic notch is preserved during the arterial systole taking place under such altered circumstances is noteworthy, and shows the essentiality of this event. It was remarking the presence of this notch which first made me suspect that the sloping ascent of the inverted tracing was not equivalent to the ascent of the ordinary.

The chief practical lesson to be derived from the foregoing statements is, that we need, in using the Sanderson-Marey sphygmograph, to be very careful that the brass plate is so placed as not to rest upon the artery. If the artery is pressed on by the spring and the brass plate, the pressure of the latter being materially the greatest, the amplitude of the tracing may be factitiously increased. If the brass plate alone press on the artery the tracing will be reversed. I think the arch in the middle of the plate should be much wider than it is often made.

III. "Note on the Discharge of Ova, and its relation in point of Time to Menstruation." By JOHN WILLIAMS, M.D. Lond., Assistant Obstetric Physician to University College Hospital. Communicated by Dr. SHARPEY, F.R.S. Received April 7, 1875.

It is a recognized fact in physiology that ova are discharged in connexion with the menstrual function, but it is uncertain at what time in the course of the month the separation takes place. It is generally understood to occur towards the end of the discharge, or immediately after its cessation. I have, however, reason to believe, from observations made in several subjects, that such is not the case, but that it takes place before the appearance of the monthly flow with which it is connected. The cases which have come under my observation fall into four series, as follows :—

A. Cases, six in number, in which a Graafian follicle had been matured and actually ruptured.

of these was a young girl who died through the effects of four days before the expected return of the catamenia. It was a recently ruptured Graafian follicle. The cavity was about  $\frac{3}{4}$  inch in diameter, and contained a recent clot, slightly through the rupture; the clot was of a fresh red color and adherent to the parts around, for on making a section it fell out. The wall of the vesicle was of a pale color and slightly wrinkled. The rupture had evidently taken place only before death.

The subject was a woman who died suddenly through a fall, eight days after the cessation of the last menstrual flow. On dissection a considerable quantity of blood was found in the cavity of the peritoneum and the liver was torn. In the left ovary was a rupture with corrugated and collapsed walls; its cavity contained a small amount of fluid and there was a slight effusion between its lining membrane and the outer coat. The depth of the follicle from the rupture to the opposite wall measured nearly  $\frac{3}{4}$  inch. It is not probable that this follicle was ruptured somewhat prematurely by the

example was observed during life. Mr. Christopher performed an ovariotomy on a patient on the fourteenth day after the last catamenial discharge. Menstruation lasted

six days after the cessation of the catamenia. On the surface of the right ovary was a small cicatrix, beneath which was a corpus luteum with the following characters:—It was of an irregular, elongated shape, nearly  $\frac{1}{2}$  inch in length and  $\frac{1}{4}$  in width; had thick, yellow, convoluted walls, and enclosed a small whitish mass, in which were two dark-coloured spots, which were evidently the remains of a clot. This ovary contained also a Graafian follicle of the size of a small pea. The determination of the age of effused blood is always difficult. In the Graafian follicle which becomes ruptured without impregnation taking place it is known that certain definite changes occur; the wall of the vesicle becomes thick, yellow, and convoluted; the blood which flowed into it and filled it becomes decolorized and absorbed. The exact length of time in which these changes in the follicle are brought about is not accurately determined, but it is known that the corpus luteum of one menstruation has become considerably atrophied by the return of the next.

It appears to me that the yellow body in the last example of this group was considerably older than the two preceding ones, and that it was more than a fortnight old, and that the two preceding ones were from eight to ten days.

B. Cases, four in number, in which a Graafian follicle had been matured, and hæmorrhage had taken place into its cavity, but no actual rupture had occurred.

(1) The first case was a patient who died of pyæmia in the third week after the cessation of the last catamenial flow. The left ovary contained a follicle  $\frac{3}{4}$  inch in diameter, distended by a recent non-adherent, softish coagulum, uniform in consistence and colour. This follicle was prominent above the adjacent surface of the ovary; and its superficial wall was thick, and presented no tendency to point or rupture. There was no recent rupture to be seen on the surface of either ovary.

(2) The second example was a woman who had undergone an operation for fistula in ano. The monthly flow made its appearance a week before the expected time for its return, and she died five days after. One ovary contained a follicle measuring  $\frac{5}{8}$  inch by  $\frac{1}{2}$  inch; this follicle contained a bright red, fresh, loose clot, and its walls were thin and not corrugated. From these characters it appears that the hæmorrhage into the follicle had taken place but a short time before death.

(3) The next was a patient who had undergone an operation for the removal of an ovarian tumour. She died a fortnight after the operation, when she had menstruated for one day. At the inner extremity of the left ovary was a large, dark-coloured, softish mass, which, on section, proved to be a Graafian follicle containing a brick-red-coloured clot, which appeared to be of a spongy texture. It could with difficulty be turned out of the sac. After its removal it was seen that the wall of the sac was formed by a thin yellowish substance.

(4) The last example in this group was a person who suffered with fibroid tumour of the uterus. She died on the third or fourth day of the

. Williams on the Discharge of Ova, and [May 27,

Both ovaries were bound to the surrounding structures by false membranes. The left contained a follicle nearly empty, in which was found a softish, dark-coloured clot, having the appearance of a coagulum, which appeared to be several days old.

Second and third members of this group hæmorrhage had taken place in the follicle unquestionably before the appearance of the catamenia.

Fourth, hæmorrhage had occurred before the flow had become regular, owing to surgical interference, having returned a second time, the hæmorrhage took place while the discharge was continuing.

From the condition of the clot makes it almost certain that hæmorrhage had taken place before the appearance of the catamenia. In one ovary in which a Graafian follicle had matured, but where neither hæmorrhage had actually occurred.

Fifth, a patient who died of typhoid fever just before the appearance of the catamenia. In one ovary there was an enlarged Graafian follicle, which was highly vascular, and projected like a nipple beyond the surface. It was evidently on the point of bursting, and it is probable that either rupture of the follicle or the appearance of the catamenia had taken place first.

Sixth, in a number, in which no Graafian follicle had become matured.

a periodical discharge was imminent, though the ovaries contained no matured Graafian follicle. It is not improbable that the follicles which were found in the three last cases, and which were enlarged to the size of a small pea, would have become mature by the next return of the flow.

I have carefully considered the cases recorded by Cruikshank, Jones, Paterson, Lee, Girdwood, Negrier, Coste and others, and find that, though they do not contribute materially to the solution of the question discussed in this paper, yet, in so far as they go, they favour the view put forward here—a view which derives support from the custom imposed by the Levitical law, and observed to this day by the stricter sect of the Hebrew community.

Postscript. Received June 10, 1875. Communicated by  
Dr. SHARPEY, F.R.S.

Since writing the above, I have had opportunities to examine two subjects in whom the date of the last menstruation was known.

The first was a girl aged 17 years, who died on the fifth day after admission to the Middlesex Hospital of traumatic tetanus. She was said to have ceased to menstruate just before admission; and the condition of the inner surface of the uterus confirmed that statement. The uterus and ovaries were small and imperfectly developed. On the surface of the right ovary was found a patch  $\frac{1}{2}$  inch in diameter, slightly injected, and presenting a punctated appearance. In its centre was a cicatrix, appearing as a white spot, beneath which was situated a yellow body, elongated and irregularly flattened in shape. This appeared to be due to pressure from several Graafian follicles growing in close proximity to it, the largest of which was as large as a small pea. The yellow body measured nearly  $\frac{1}{2}$  inch in length; it had folded walls, and in its centre was a thin elongated clot, the middle of which was of a dark colour.

The second subject was aged 26 years; she died of Bright's disease. The last menstruation began May 13th, ceased May 19th, and death occurred May 28th, 15 days after the appearance of the flow. Hæmorrhage had taken place into the superficial tissue of the ovaries, probably by reason of the condition of the blood.

In the right was a small superficial prominence formed by a yellow body, which measured about  $\frac{3}{8}$  inch in diameter; it was throughout of a yellowish colour, and contained no trace of the colouring-matter of blood. On comparing these organs with one another and with those previously described, I am led to infer that in the first 12 to 14 days, and in the second about 20 days had elapsed since rupture of the follicle occurred.

Reichert has examined 23 organs in which signs of menstruation were recognizable. In four cases a Graafian follicle had matured but not ruptured, nor had hæmorrhage taken place, though the decidua menstrualis was in a state of greater or less development; in eighteen cases a Graafian follicle

*Mallet on the Mechanism of Stromboli.* [May 27,

hæmorrhage had taken place into the decidua; in one case preceding had not begun, had a Graafian follicle been ruptured. This statement appears opposed to the conclusions at which I have arrived, but this is only apparent; for in one case a follicle had ruptured, and a Graafian follicle had matured before hæmorrhage began, and in the other the rupture was on the eve of taking place; in eighteen cases the rupture had taken place, and hæmorrhage had taken place into the decidua. In this form, Reichert's cases are not opposed to the conclusions arrived at in the preceding note; and as his cases have not been examined, it is not possible to say what their actual bearing may be. Reichert has arrived at by Reichert, after examination of the 23 specimens, that rupture of the Graafian follicle takes place at an early period of the menstrual flow.

*Mr. Mallet's Paper on the Mechanism of Stromboli.*  
ROBERT MALLETT, F.R.S. Received May 21, 1875.

In the appearance of my paper on Stromboli some strictures hostile to the conclusions contained have been published†, in which it is urged that the crater of the fundus, or bottom of the visible crater, which is situated at 300 to 400 feet above the sea, is greatly below the level of the crater, which is affirmed, at least 2000 feet above the sea-level. It is

V. "Electrodynamic Qualities of Metals. (Continued from Phil. Trans. for February 28, 1856.)—Part VI. Effects of Stress on Magnetization." By Prof. Sir W. THOMSON, LL.D., F.R.S. Received May 27, 1875.

(Abstract.)

Weber's method, by aid of electromagnetic induction and a "ballistic galvanometer" to measure it, which has been practised with so much success by Thalén, Roland, and others, has been used in the investigation of which the results are at present communicated; but partial trials have been made by the direct magnetometric method (deflections of a needle), and this method is kept in view for testing slow changes of magnetization which the electromagnetic method fails to detect.

The metals experimented on have been steel pianoforte-wire, of the kind used for deep-sea soundings by the American Navy and British cable-ships; and soft-iron wires of about the same gauge, but of several different qualities.

I. *Steel.*

The steel wire weighs about  $14\frac{1}{2}$  lbs. per nautical mile and bears 230 lbs. Weights of from 28 lbs. to 112 lbs. were hung on it and taken off, and results described shortly as follows were found:—

(1) The magnetization is diminished by hanging on weights, and increased by taking the weights off, when the magnetizing current is kept flowing.

(2) The residual magnetism remaining after the current is stopped is also diminished by hanging on the weights, and increased by taking them off.

(3) The absolute amount of the difference of magnetization produced by putting on and taking off weights is greater with the mere residual magnetism when the current is stopped than with the whole magnetism when the magnetizing current is kept flowing.

(4) The change of magnetization produced by making the magnetizing current always in one direction and stopping it is greater with the weights on than off.

(5) After the magnetizing current has been made in either direction and stopped, the effect of making it in the reverse direction is less with the weights on than off.

(6) The difference announced in (5) is a much greater difference than that in the opposite direction between the effects of stopping the current with weights on and weights off, announced in (4).

(7) When the current is suddenly reversed, the magnetic effect is less with the weights on than with the weights off.

*II. Soft-Iron Wires.*

at the same gauge as the steel were used, but, except one only about 28 lbs. instead of 230. All of three or four agreed with the steel in (1).

It behaved (except a seeming anomaly, hitherto unexplained in a reverse manner to steel in respect to (2), (4), (5), and (6); the steel in respect to (7). Another iron wire\*, which, "soft," was much less soft than the first, agreed with steel in (1) and (2), but [differing from steel in respect to (3)] the effects of weights on and off when the magnetizing current was stopped when it was stopped.

On wires which were very soft, softer even than the first, the steel and iron wires in respect to (1), but gave results for (2) which proved an exceedingly transient residual magnetism, and were otherwise seemingly anomalous.

Work is being continued with special arrangements to find out the cause of these apparent anomalies, and with the further object to obtain in absolute measure the amounts of all the proved effects at temperatures up to 100° Cent.

The meeting then adjourned over the Election-day, to Thursday,

Thanks were given to the Scrutators.

June 10, 1875.

JOSEPH DALTON HOOKER, C.B., President, in the Chair.

The Presents received were laid on the table, and thanks ordered for them.

Dr. James Risdon Bennett, Mr. James Caird, Mr. James Whitbread Lee Glaisher, Mr. J. Baboneau Nickterlien Hennessey, Mr. William Chandler Roberts, and Major-General Henry Young Darracote Scott were admitted into the Society.

The following Papers were read:—

I. "A Memoir on Prepotentials." By Prof. CAYLEY, F.R.S.  
 Received April 8, 1875.

(Abstract.)

The present memoir relates to multiple integrals expressed in terms of the  $(s+1)$  ultimately disappearing variables  $(x \dots z, w)$ , and the same number of parameters  $(a \dots c, e)$ , and being of the form

$$\int \frac{\rho d\omega}{\{(a-x)^2 \dots + (c-z)^2 + (e-w)^2\}^{\frac{1}{2}s+q}}$$

where  $\rho$  and  $d\omega$  depend only on the variables  $(x \dots z, w)$ . Such an integral, in regard to the index  $\frac{1}{2}s+q$ , is said to be "prepotential," and in the particular case  $q = -\frac{1}{2}$  to be "potential."

I use throughout the language of hyper-tridimensional geometry:  $(x \dots z, w)$  and  $(a \dots c, e)$  are regarded as coordinates of points in  $(s+1)$ -dimensional space, the former of them determining the position of an element  $\rho d\omega$  of attracting matter, the latter being the attracted point; viz. we have a mass of matter  $= \int \rho d\omega$  distributed in such manner that  $d\omega$  being the element of  $(s+1)$ - or lower-dimensional volume at the

), the corresponding density is  $\rho$ , a given function of  $\omega$  such that the element of mass  $\rho d\omega$  exerts on the attracted point a force proportional to the  $(s+2q+1)$ th power of the distance,  $\{(\epsilon-x)^2 + (\epsilon-z)^2 + (\epsilon-w)^2\}^{\frac{s+2q+1}{2}}$ . The integration is extended over the whole attracting mass  $\int \rho d\omega$ ; and the integral is then called the prepotential of the mass in regard to the point  $\epsilon$ . In the particular case  $s=2$ ,  $q=-\frac{1}{2}$ , the force is as the inverse square of the distance, and the integral represents the potential in the ordinary sense of the word.

The element of volume  $d\omega$  is usually either the element of solid  $(s+1)$ -dimensional volume  $dx \dots dz dw$ , or else the element of  $s$ -dimensional volume  $dS$ . In particular, when the surface (locus) is the  $(s$ -dimensional) plane  $w=0$ , the superficial element is  $dx \dots dz$ . The cases of a less-than- $s$ -dimensional volume are not in the present memoir considered only incidentally. It is scarcely necessary to remark that the notion of density is dependent on the dimension of the element of volume  $d\omega$ : in passing from a spatial distribution,  $\rho dx \dots dz dw$ , to a superficial distribution,  $\rho dS$ , we alter the meaning of  $\rho$ . In fact if, in order to connect the two, we imagine the superficial distribution as made over an indefinitely thin layer or stratum of thickness  $dw$  on the surface, so that at any element  $dS$  of the surface the corresponding element of volume is  $d\omega$ , where  $d\omega$  is a function of the coordinates  $(x, \dots, z, w)$  such that the element of mass is  $\rho d\omega$  and the element of mass

stated, assumed that the attracted point does not lie on the material surface; to make it do so is, in fact, a particular supposition. As to solid integrals, the cases where the attracted point is not, and is, in the material space may be regarded as cases of coordinate generality; or we may regard the latter one as the general case, deducing the former one from it by supposing the density at the attracted point to become  $=0$ .

The present memoir has chiefly reference to three principal cases, which I call A, C, D, and a special case, B, included both under A and C: viz. these are:—

A. The prepotential-plane case;  $q$  general, but the surface is here the plane  $w=0$ , so that the integral is

$$\int \frac{\rho \, dx \dots dz}{\{(a-x)^2 \dots + (c-z)^2 + e^2\}^{\frac{1}{2}e+q}}.$$

B. The potential-plane case;  $q = -\frac{1}{2}$ , and the surface the plane  $w=0$ , so that the integral is

$$\int \frac{\rho \, dx \dots dz}{\{(a-x)^2 \dots + (c-z)^2 + e^2\}^{\frac{1}{2}e-\frac{1}{2}}}.$$

C. The potential-surface case;  $q = -\frac{1}{2}$ , the surface arbitrary, so that the integral is

$$\int \frac{\rho \, dS}{\{(a-x)^2 \dots + (c-z)^2 + (e-w)^2\}^{\frac{1}{2}e-\frac{1}{2}}}.$$

D. The potential-solid case;  $q = -\frac{1}{2}$ , and the integral is

$$\int \frac{\rho \, dx \dots dz \, dw}{\{(a-x)^2 \dots + (c-z)^2 + (e-w)^2\}^{\frac{1}{2}e-\frac{1}{2}}}.$$

It is, in fact, only the prepotential-plane case which is connected with the partial differential equation

$$\left( \frac{d^2}{da^2} \dots + \frac{d^2}{dc^2} + \frac{d^2}{de^2} + \frac{2q+1}{e} \frac{d}{de} \right) V = 0,$$

considered in Green's memoir 'On the Attractions of Ellipsoids' (1835), and called here the prepotential equation. For this equation is satisfied by the function

$$\frac{1}{\{a^2 \dots + c^2 + e^2\}^{\frac{1}{2}e+q}},$$

and therefore also by

$$\frac{1}{\{(a-x)^2 \dots + (c-z)^2 + e^2\}^{\frac{1}{2}e+q}},$$

y by the integral

$$\int \frac{\rho dx \dots dz}{\{(a-x)^2 \dots + (c-z)^2 + e^2\}^{\frac{1}{2}n+s}} \dots \dots \dots (A)$$

prepotential-plane integral; but the equation is not  
value

$$\frac{1}{\{(a-x)^2 \dots + (c-z)^2 + (c-w)^2\}^{\frac{1}{2}n+s}}$$

by the prepotential-solid, or general superficial, integral.  
 $\frac{1}{2}$ , then, instead of the prepotential equation, we have

$$\left( \frac{d^2}{da^2} \dots + \frac{d^2}{dc^2} + \frac{d^2}{de^2} \right) V = 0 ;$$

sified by

$$\frac{1}{\{a^2 \dots + c^2 + e^2\}^{\frac{1}{2}n-1}}$$

also by

$$\frac{1}{\{(a-x)^2 \dots + (c-z)^2 + (c-w)^2\}^{\frac{1}{2}n-1}}$$

four distribution-theorems is the principal object of the present memoir; but the memoir contains other investigations which have presented themselves to me in treating the question. It is to be noticed that the theorem A belongs to Green, being in fact the fundamental theorem of his memoir of 1835, already referred to. Theorem C, in the particular case of tridimensional space, belongs also to him, being given in his 'Essay on the Application of Mathematical Analysis to the theories of Electricity and Magnetism' (Nottingham, 1828), being partially rediscovered by Gauss in the year 1840; and theorem D, in the same case of tridimensional space, to Lejeune-Dirichlet: see his memoir "Sur un moyen général de vérifier l'expression du potentiel relatif à une masse quelconque homogène ou hétérogène," Crelle, t. xxxii. pp. 80-84 (1846). I refer more particularly to these and other researches by Gauss, Jacobi, and others in the course of the present memoir.

"On the Fossil Mammals of Australia.—Part X. Family MACROPODIDÆ: Mandibular Dentition and Parts of the Skeleton of *Palorchestes*, with additional evidences of *Sthenurus*, *Macropus Titan*, and *Procoptodon*." By Professor OWAN, C.B., F.R.S. Received May 10, 1875.

(Abstract.)

In this "Part" the author gives additional evidences of extinct genera and species of Kangaroos defined in the two preceding Parts (VIII and IX.). To the *Palorchestes Azael* he adds characters of the mandible and mandibular teeth, and gives a restoration of the entire skull; the pelvis, femur, tibia, calcaneum, and principal bones of the hind foot of this gigantic species are described and figured.

Of *Macropus Titan* the author restores the entire skull and femur. Of *Sthenurus Atlas* he describes and figures the incisor teeth, the deciduous dentition, and the fore part of the skull of a young individual: of the larger species of this genus, *Sthenurus Brehus*, the entire skull and dentition are restored. The "Part" concludes with the restoration of certain bones of the hind foot in a Kangaroo slightly exceeding the largest *Macropus major* in size (indicated as a *Macropus affinis*), in the *Phascolagus altus*, in *Palorchestes Azael*, and in the three species of *Procoptodon* (*Pusio*, *Rapha*, and *Goliath*). The paper concludes with remarks on the transitionary character of the latter forms, as bridging the gap between the saltigrade and gravigrade groups of phyliphaeous Marsupialia.

The paper is illustrated by subjects for thirteen plates.

Organization of the Fossil Plants of the Coal-measure.  
Part VII. *Myelopteris*, *Psaronius*, and *Kaloxylon*."

W. C. WILLIAMSON, Professor of Natural History in the University of Manchester. Received June 3, 1875.

## (Abstract.)

Dr. Schimper first figured some supposed stems under the name of *Medullosa*, to one of which he gave the name of *Medullosa*. He subsequently figured a portion of the same plant, in his 'Paläontologie,' under the name of *Palmacites carbonigerus*, in the opinion that it was the stem of an arborescent palm. M. Brongniart next gave it the name of *Myeloxylon*, and at the same time expressed doubts respecting its monocotyledonous character. Goebel gave it the generic name of *Stengelia*. In 1872 Mr. Williamson expressed his belief that the plant was "the rachis of a fern, or a rachis to one." At the Meeting of the British Association at Manchester in September 1873, the author described this plant, and gave his reasons for believing it to be not only a fern, but to belong to the interesting family of the Marattiaceæ; and in the subsequent year Professor Renault read a description of the plant to the Académie des Sciences at Paris, when, on independent evidence, he arrived at the same conclusion, viz. that it was one of the Marattiaceæ. Slightly

a canal, of varied sizes and shapes, which appears to have been originally a gum-canal, subsequently enlarged irregularly by the shrinking of the neighbouring tissues. In the larger and more matured petioles these vascular bundles are very conspicuous, both in transverse and longitudinal sections; but in the small, young, and terminal subdivisions of the rachides the vessels are so small as to be almost undistinguishable from the surrounding parenchyma, while the gum-canals of such examples are, on the other hand, conspicuously large. Transverse sections of the most perfect examples of these young rachides exhibit, on their upper surface, a rounded central ridge, flanked on either side by a longitudinal groove, which arrangements are so conspicuous in the corresponding portions of the petioles of the Marattiaceæ and of other ferns. The ultimate leaflet-petioles were given off at right angles to the central rachis from which they sprang, corresponding in this respect with one of the types described by M. Renault. The author has not yet found in Lancashire any of the large specimens that have been met with on the continent at Autun and in the localities whence M. Cotta obtained his examples. He has found a few and yet smaller fragments among the sections from Burntisland. The recognition of the Marattiaceous character of these plants excludes the *Palmaceæ* for the present from all claim to share in the glories of the carboniferous vegetation.

The second plant described by the author consists of clusters of roots with a portion of the outermost parenchymatous layer of the stem of a tree fern, corresponding to those of the *Psaronites* long known to characterize the upper carboniferous deposits of Autun and other localities. The roots of the Oldham specimen, to which the author has assigned the name of *Psaronites Renaultii*, consist of a well-defined cylinder of sclerenchymatous prosenchyma, within which has been a mass of more delicate parenchyma, in the centre of which was the usual vascular bundle. But what characterizes the specimens, distinguishing them from the numerous species described by Corda, is the existence of vast numbers of cylindrical hairs, each composed of a linear row of elongated cylindrical cells: these have obviously been the absorbent root-hairs of the living plant, which may possibly have been some species of *Stemmatopteris*; but of this there is as yet no evidence.

The author then describes a small but very remarkable stem, to which he assigns the name of *Kaloxylon Hookeri*. This is a slender stem, rarely more than from one seventh to one tenth of an inch in diameter. In its young state it consists of a central vascular axis which has an hexagonal section, and which is composed of numerous vessels of various sizes, each of which exhibits the reticulate form of the scalariform or barred type, and which is so common amongst the plants of the Coal-measures. No true barred or spiral vessels have yet been seen in the *Kaloxylon*. In the young twigs this vascular axis is surrounded by a mass of large-celled cortical parenchyma, which, in turn, is encased by an epidermal struc-

of a double row of what have evidently been colourless  
are elongated vertically, but with square ends.  
matured stems, the central vascular axis of the young  
the centre whence radiate six exogenously developed  
lar tissue, each of which enlarges as it proceeds out-  
nates at its outer extremity in a slightly rounded con-  
edge consists of a series of radiating vascular laminae,  
merous medullary rays, which latter consist of long and,  
rt, single vertical rows of mural cells. These six exo-  
are separated from each other by a large wedge of cellular  
yma, the cells of which are elongated radially and have a  
l arrangement. As those between any two contiguous  
outwards, they separate more or less definitely into two  
erge right and left to sweep round the peripheral extremity  
exogenous wedge, meeting and blending with a similar set  
e opposite side of the wedge. In doing this they form a  
nclosing a semilunar mass of smaller cells interposed  
o and the outer end of the exogenous wedge. The author  
at this enclosed cellular tissue is essentially a cambial  
hich all the new vessels and peripheral extensions of  
ays were developed. Young vessels are seen at its  
process of formation. External to these two specialized

that its occurrence is not merely a question of the size of the plant, as some have supposed, but that it has a deeper meaning, and corresponds more closely than has been supposed with the exogenous developments seen equally in large and small examples of living plants.

IV. "Experiments on Stratification in Electrical Discharges through Rarefied Gases." By WILLIAM SPOTTISWOODE, M.A., Treas. R.S. Received May 27, 1875.

In the stratified discharges through rarefied gases produced by an induction-coil working with an ordinary contact-breaker, the striæ are often unsteady in position and apparently irregular in their distribution. Observations made with a revolving mirror, which I hope to describe on another occasion, have led me to conclude that an irregular distribution of striæ does not properly appertain to stratification, but that its appearance is due to certain peculiarities in the current largely dependent upon instrumental causes.

The beautiful and steady effects obtained by Mr. Gassiot with his Leclanché battery, and also more recently by Mr. De La Rue with his chloride-of-silver battery, have abundantly shown the possibility of stratification free from the defects above mentioned; but it must be admitted that the means employed by those gentlemen are almost gigantic. The present experiments were undertaken with the view of ascertaining, first, how far it was possible to approach towards similar results with instruments already at my command; and secondly, whether these would afford other modes of attack, beside the battery, on the great problem of stratified discharges.

The induction-coil used was an "18-inch" by Apps, worked occasionally by 6 large chloride-of-silver cells, kindly lent to me by Mr. De La Rue, but more usually by 10 or by 20 Leclanché cells of the smallest size ordinarily made by the Silvertown Company. I have also, in connexion with the same coil, 120 of the latter cells, connected in twenties for quantity, and forming 6 cells of 20 times the surface of the former: these work the coil with the ordinary contact-breaker very well, giving 11-inch sparks whenever required. A "switch" affords the means of throwing any of the three batteries in circuit at pleasure.

Having reason to think that the defects in question were mainly due to irregularity in the ordinary contact-breaker, I constructed one with a steel rod as vibrator (figs. 1 & 2, p. 456), having a small independent electromagnet for maintaining its action. The natural vibrations of the rods which were tried varied from 320 to 768 per second; while under the action of the battery-current and electromagnet they varied from 700 to 2500, or thereabouts, per second. The amplitudes of the vibrations were exceedingly small, in fact not exceeding .01 of an inch; and it is to this fact,

Fig. 1.

*Elevation of Contact-breaker. Half size (linear).*

Fig. 2.

*Elevation of Contact-breaker. Half size (linear).*

coupled with the extreme rapidity and consequent decision of make and break, that I mainly attribute the steadiness of the results.

The rod bore a plate of platinum, hammered hard, on its upperside; and when contact was made this plate met a thin platinum pin connected with the circuit. In order to avoid, as far as possible, any uncertainty in contact, the diameter of this pin was small; and one difficulty to be obviated was the heating and even fusion of the platinum when the circuit was completed. This was met by using the small-sized cells mentioned above, and employing a fine copper wire (No. 26) round the electromagnet. The very slight "strength of current," or minute "quantity," required for the illumination of vacuum-tubes made it possible so to reduce the surface of the battery-cells and the diameter of wire as to render the overheating in a great measure avoidable. This reduction of dimensions, however, is limited, first, by the amount of magnetism required to keep up the vibrations, and, secondly, by the diameter of the tubes used for the experiments; for it is obvious that, since wire and tube both form parts of the same circuit, in order to produce an equal illumination (other things being the same), we must for a tube of large diameter use a thicker wire than would be necessary for one of small diameter.

With a contact-breaker of this kind in good action, several phenomena were noticeable; but first and foremost was the fact that, in a large number of tubes (especially hydrocarbons), the striæ, instead of being sharp and flaky in form, irregular in distribution, and fluttering in position, were soft and rounded in outline, equidistant in their intervals, and steady in proportion to the regularity of the contact-breaker. These results are, I think, attributable more to the regularity than to the rapidity of the vibrations. And this view is supported by the fact that, although the contact-breaker may change its note (as occasionally happens), and in so doing may cause a temporary disturbance in the stratification, yet the new note may produce as steady a set of striæ as the first: and not only so, but frequently there is heard, simultaneously with a pure note from the vibrator, a strident sound, indicating that contacts of two separate periods are being made; and yet, when the strident sound is regular, the striæ are steady. On the other hand, to any sudden alteration in the action of the break (generally implied by an alteration in the sound) there always corresponds an alteration in the striæ.

It is difficult to describe the extreme delicacy in action of this kind of contact-breaker, or "high break," as it may be called. The turning through  $2^\circ$  or  $3^\circ$  of a screw, whose complete revolution raises or lowers the platinum pin through  $\cdot 025$  of an inch, is sufficient to produce or to annihilate the entire phenomenon. A similar turn in a screw forming one foot of the pedestal of the break is enough to adjust or regulate the striæ; and a slight pressure of the finger on the centre of the mahogany

rigid, or even on the table on which the contact-breaker control their movements.

described above are usually (although not always) those making contact; but it often happens, and that most frequently, that the strident noise is heard, that the current produced by is strong enough to cause a visible discharge. This happens as with the high break; but in the latter case the presents the very remarkable peculiarity that the strise of so arranged as to fit exactly into the intervals of the other, that any disturbance affecting the column of strise affects similarly, with reference to absolute space, that so that the double column moves, if at all, as a solid or and this fact is the more remarkable if we consider, as is a revolving mirror, that these currents are alternate, not but also in time, and that no one of them is produced until the extinction of its predecessor. And it is also worthy association of strise is not destroyed even when the two rated more or less towards opposite sides of the tube by magnetic pole. There seems, however, to be a tendency the strise of one current to advance upon the positions of the reverse current, giving the whole column a ce. But as there is no trace, so far as my observations of alternat. discharges when produced by the ordi-

assistant, Mr. P. Ward, to whose intelligence and skill I am much indebted throughout this investigation, intended for fine adjustment. Wherever the resistance be introduced the following law appears to be established by a great number and variety of experiments, viz. that, the striæ being previously stationary, an increase of resistance produces a forward flow, a decrease of resistance a backward flow. I have generally found that a variation of 3 or 4 ohms, or, under favourable conditions, of 1 or 2 ohms, in the primary current is sufficient to produce this effect. But as an alteration in the current not only affects the discharge directly, but also reacts upon the break, the effect is liable to be masked by these indirect causes. The latter, so far as they are dependent upon a sudden alteration of the resistance, may be diminished by the use of the rheostat; but when the striæ are sufficiently sensitive to admit the use of this delicate adjustment, some precautions are necessary to insure perfect uniformity of current, so as to avoid disturbances due to uneven contact in the rheostat itself.

When the striæ are flowing they preserve their mutual distances, and do not undergo increase or decrease in their numbers. Usually one or two remain permanently attached to the positive electrode; and as the moving column advances or recedes, the foremost stria diminishes in brilliancy until, after travelling over a distance less than the intervals between the two striæ, it is lost in darkness. The reverse takes place at the rear of the column. As the last stria leaves its position, a new one, at first faint and shadowy, makes its appearance behind, at a distance equal to the common interval of all the others: this new one increases in brilliancy until, when it has reached the position originally occupied by the last stria when the column was at rest, it becomes as bright as the others. The flow may vary very much in velocity; it may be so slow that the appearances and disappearances of the terminal striæ may be watched in all their phases, or it may be so rapid that the separate striæ are no longer distinguishable, and the tube appears as if illuminated with a continuous discharge. In most cases the true character of the discharge and the direction of the flow may be readily distinguished by the aid of a revolving mirror. In some tubes, especially in those whose length is great compared with their diameter, the whole column does not present the same phase of flow; one portion may be at rest while another is flowing, or even two conterminous portions may flow in opposite directions. This is seen also in very wide tubes, in which the striæ appear generally more mobile than in narrow ones. But in all cases these nodes or junction-points of the flow retain their positions under similar conditions of pressure and current; and it therefore seems that, under similar conditions, the column in a given tube always breaks up into similar flow-segments.

These nodes will often disappear under the action of a magnetic pole. Thus if the first segment, measured from the positive terminal, be sta-

second be flowing backwards (i. e. from - to +), a magnetic strength, placed at the distant end of the latter, and the whole column will become stationary through-  
out in the strength of the magnet, or a nearer approach will produce a general forward flow of the column.

Some of the flow, as well as others of not less interest, are produced with the Holtz machine. It is well known that discharges, similar to those produced by an induction-coil at an ordinary break, may be produced by such a machine, and may be furnished with the usual Leyden jars, and a high resistance (by a piece of wetted string) be interposed in the circuit. Neither of these conditions was supposed to destroy the continuity of the discharge continuous. Experiments which I have not do not describe on the present occasion, tend in part, to confirm this view. They show that for the production of a certain quantity and resistance are necessary, that the discharge occupy a certain short, perhaps, but finite time, or, as it may be expressed, that a continuous current is an essential

condition that every tube must offer some resistance, and also that the height of the vertical condensers of the machine (or the resistance interposed in the circuit) we had the means of altering the discharge, it seemed worth while to try whether

tion, the effects with the Holtz machine were very striking: the striæ, with steady revolution of the machine, became fixed in position and well defined. This tube, some carbonic-acid-gas tubes, and one or two others, generally containing acid residua, form a class in which the action of the machine more nearly approaches that of Mr. Gassiot's battery than in any others. The striæ thus formed were not easily brought into a state of flow; but an increase in the rapidity of the machine, or a diminution of resistance, increased the number of the striæ. As the rapidity was augmented, the striæ might be seen pouring themselves out, as it were, from the positive pole; the length of the column was slightly increased, but by no means in proportion to the number of striæ.

One modification of this effect, although almost fantastic in its appearance, seems to deserve a special notice. It is well known that if a sufficient interval of air be thrown into the circuit all trace of stratification disappears, and at the same time the dark interval between the positive and negative parts and the negative halo itself are obliterated. If, however, the interval of air be very small, the two kinds of discharge may be seen coexisting; a narrow column of the continuous discharge extends along the tube, and on it the striæ appear to be strung. These effects are easily produced by slightly lowering one of the vertical conductors of the machine; and perhaps the best effects are shown if the conductor on the side connected with the positive terminal of the tube is lowered. When this is done the striæ occupying the portion nearest to that terminal become widely separated at unequal and varying intervals; they appear to oscillate along the tube with independent motions, as if attached to an elastic string which at each instant is unequally stretched at its various parts. The portion of the column so affected varies with the length of the interval of air; and when, for instance, that portion amounts to two thirds of the entire length, the striæ in the remaining third appear crowded together. As the interval of air is further increased more striæ become disturbed, the continuous discharge becomes wider and more prominent, and ultimately overpowers and obliterates the striæ.

The resistance-coil used for the secondary current or the machine consists of a hollow glass spiral, A A A (fig. 3), having a length of about 50 inches and an internal diameter of  $\frac{1}{8}$  of an inch. At the head is a small glass bulb B, having an opening at the top, which is closed by a glass stopper. A platinum wire, N, connected with one of the terminals, H, dips to the bottom of the bulb B, which is partially filled with sulphuric acid. C is a small glass bulb containing mercury, and is connected with the lower end of the spiral by a flexible tube, D. The height of this bulb can be regulated by means of the slide F, which moves on the steel rod E. P is a small platinum wire fused into the interior of the bulb G, and is in connexion with the other terminal, H.

If the bulb C be placed in any position, the mercury will rise in the spiral to the same level as that in the bulb. The mercury will act

V. "Electrolytic Conduction in Solids.—First Example. Hot Glass." By Prof. Sir WILLIAM THOMSON, F.R.S. Received June 10, 1875.

Many years ago I projected an experiment to test the voltaic relations between different metals with glass substituted for the electrolytic liquid of an ordinary simple voltaic cell, and with so high a temperature that the glass would have conducting-power sufficient to allow induction through it to rule the difference of potentials between the two metals. Imperfect instrumental arrangements, and want of knowledge of the temperature at which glass would have sufficient conductivity to give satisfactory results, have hitherto prevented me from carrying out the proposed investigation. The quadrant electrometer has supplied the first of these deficiencies, and Mr. Perry's recent experiments\* on the conductivity of glass at different temperatures the second. The investigation has now been resumed; and in a preliminary experiment I have already obtained a very decided result.

The drawing shows the arrangement adopted. MN is a brass case immersed in an oil-bath. A copper plate, C, of 5 centims. diameter, lies in the case on a block of wood; it is kept metallically connected with the outside case, E, of the electrometer. A flint-glass plate, G, which is

found to insulate very well at ordinary temperatures, is laid upon C. A zinc plate, Z, lies on the glass, and is connected with the insulated electrode, I, of the electrometer, by means of a wire attached to the end of a stout metallic stem, A Z, passing through the centre of an open vertical tube reaching above the level of the oil. The glass was heated gradually, and was usually kept between  $100^{\circ}$  and  $120^{\circ}$  C., the temperature being measured by a thermometer, B.

Even below  $50^{\circ}$  C. there is a decided result, but shown less rapidly

\* See *infra*, p. 468.

temperatures. If the glass is kept at  $50^{\circ}\text{C}$ . for some time after having been metallically connected with P, is left insulated, it becomes sensibly charged; and the charge increases till it is ultimately equal to that acquired when zinc and copper and electrolyte are metallically connected with I and E. With the hot glass, as with the liquid electrolyte, the charge on the zinc to the insulated electrode of the electrometer is the same as the charge ultimately reached when the temperature is  $50^{\circ}$  is not reached at higher temperatures; but, as said above, when the zinc is connected with the copper and then insulated, the charge increases to its ultimate value much more rapidly at higher temperatures

between  $100^{\circ}$  and  $120^{\circ}\text{C}$ . there is a sensible diminution of the ultimate charge after the zinc has been kept for a short time connected with the copper and then insulated. There is also a slow decay of the ultimate, or, as we may now call it, the temporarily static charge when the zinc plate is left insulated for several hours in the hot glass.

If a quantity of either negative or positive electricity be given to the glass (without metallic connexion with the zinc), the temporarily static charge decays at about the same rate as the zero would be reached by the glass through the hot glass (according to Mr. Perry's experiments,

VI. "Note on Dulong and Petit's Law of Cooling." By DONALD MACFARLANE. Communicated by Prof. Sir W. THOMSON, F.R.S. Received June 10, 1875.

The 'Journal de Physique' for December 1873 contains a friendly notice by Professor A. Cornu of experiments made to determine surface-conductivity for heat (or, as we may call it, "thermal emissivity") in absolute measure, an account of which was communicated to the Royal Society, and read January 1872 (see Proceedings, vol. xx. p. 90). On the results there given M. Cornu remarks:—

"Ces nombres vérifient la conclusion de Dulong et Petit, à savoir que les vitesses de refroidissement ne dépendent de l'état des surfaces que par une constante de proportionnalité.

"L'accélération négative du rapport des pouvoirs émissifs n'infirmé pas sensiblement cette conclusion; elle est si faible qu'elle peut être attribuée à une petite erreur régulière dans l'évaluation des différences de température; en effet, l'auteur ne paraît tenir aucun compte d'une cause délicate d'erreur qui avait préoccupé Dulong et Petit, à savoir la résistance inégale à la transmission de la chaleur dans les deux cas. Il est évident que, dans le refroidissement le plus rapide, la température est distribuée moins uniformément que dans le cas d'un refroidissement lent; l'aiguille thermoélectrique indique donc moins bien la température moyenne de la masse que les boules de mercure des physiciens français."

On this it is to be remarked that a rigorous proportionality in the rates of cooling of different surfaces is in itself not probable; and my experiments in fact disprove it, so far as it is not at all likely that the errors of observation could be so great or so consistently regular in the same direction as the truth of the supposed law would require.

As to the variation of temperature from centre to surface occasioned by the rapid cooling of the ball, this was certainly not overlooked in planning the experiments. Sir William Thomson considered the matter carefully, and selected copper, on account of its high conductivity, estimating that in a copper ball of the dimensions used (diameter 4 centimetres) the temperature must be sensibly uniform throughout. A very simple calculation (made in consequence of M. Cornu's criticism, and appended below) from Fourier's celebrated formula for the cooling of a homogeneous solid globe shows, in fact, that, in the case of a copper globe of 2 centimetres radius, the centre is warmer than the surface by only about  $\frac{1}{4000}$  of the excess of its temperature above that of the surrounding medium. There would be a much greater difference of temperature between surface and centre in a globe of mercury of the same dimensions, because mercury is a much worse conductor of heat than copper, and because a much greater difference of temperatures than that which there is in the copper would be required to produce any considerable convection of heat by currents in the liquid. Moreover the glass envelope con-

mercury in a thermometer-bulb of ordinary dimensions produces a difference of temperature between the outer surface of the glass and the surface of the mercury. Let  $b$  be the thickness of the glass,  $E$  the "emissivity" of its outer surface,  $k$  the conductivity of its substance; let the excess of temperature of the outer surface of the glass above that of the surrounding medium be  $\delta v$ , and the excess of temperature of the inner surface of the glass be  $v$ ; we have

$$k \frac{\delta v}{b} = Ev.$$

From Glasgow experiments it has been found that  $E$  is approximately equal to 1 gramme-water thermal unit per square centimetre per degree. By the determinations of conductivities of stones and metals made by Peclet and Forbes the value of  $k$  may be roughly estimated at  $\frac{1}{10}$ , in terms of centimetre, gramme-water thermal unit. Hence

$$\frac{\delta v}{v} = \frac{1}{10} b.$$

If the thickness of the glass be half a millimetre (i. e.  $b = \frac{1}{20}$ ), we

any arbitrary function of  $x$  from  $x=0$  to  $x=a$ , for the value of  $v$ , when  $t=0$ :

$v$  temperature at time  $t$  and distance  $x$  from centre of globe,

$a$  the radius of the globe,

$k$  the thermal conductivity of its substance,

$c$  the thermal capacity per unit volume of its substance,

$E$  the thermal emissivity of its surface.

Taking centimetre, second, and gramme-water thermal units for the fundamental units, we have, as stated above,

$$E = \frac{1}{4000} \text{ (rough approximation) ;}$$

and Ångström's experiments gave for copper

$$k = 1 \text{ approximately.}$$

Therefore

$$\frac{Ea}{k} = \frac{a}{4000} ;$$

and for the globe of 4 centimetres diameter used in the Glasgow experiments,

$$\frac{Ea}{k} = \frac{1}{2000} .$$

In all cases in which  $\frac{Ea}{k}$  is small, the smallest root of the transcendental equation (2) is approximately equal to

$$\sqrt{\frac{3Ea}{k}} .$$

Calling this  $\varpi_1$ , we have

$$\rho_1 = \frac{3E}{ac}$$

and

$$\begin{aligned} \frac{\sin \theta_1}{\theta_1} &= 1 - \frac{1}{6} \theta_1^2 \text{ approximately,} \\ &= 1 - \frac{1}{2} \frac{Ea}{k} \frac{x^2}{a^2} . \end{aligned}$$

Now any chosen term of (1) is a particular solution of the problem ; that is to say, it is *the* solution for the case for which the initial distribution of temperature is that which it expresses when  $t=0$ . Hence

$$v = \left( 1 - \frac{1}{2} \frac{Ea}{k} \frac{x^2}{a^2} \right) e^{-\frac{3E}{ac}t}$$

temperature at time  $t$ , if when  $t=0$  the temperature is

$$t = 1 - \frac{1}{2} \frac{Ea}{k} \frac{x^2}{a^2}.$$

For instance, the copper globe of 4 centimetres diameter,

$$v = \left(1 - \frac{1}{4000} \frac{x^2}{a^2}\right) e^{-\frac{3E}{aw}t}; \quad . . . . . (3)$$

in the Glasgow experiments the difference of temperature between surface and centre was just  $\frac{1}{1000}$  of the excess of either over the temperature of the surrounding medium, when time enough had elapsed to allow the first term of Fourier's series to be the predominant one. Before that time the difference of temperatures must have been  $\frac{1}{100}$  of either, if initially the temperature was uniform throughout the globe. The Fourier analysis of the transition from the initial uniform distribution to the state represented by (3) is interesting, but unnecessary for the settlement of the present

hollow glass globe with a long stem. C is a brass insulator with pumice and sulphuric acid, to keep the stem free from moisture. C is supported on a stand resting on the table. A wooden clamp supports A B at A. B D is covered with tinfoil or with wet linen cloth. W is water inside the globe.

Fig. 1.

Fig. 2.

For a lecture illustration Mr. M'Farlane, on March 13th, 1874, charged a flint-glass jar, the globe of which was 13 centims. in diameter and about 0·13 centim. thick. The inside coating was put to earth by means of a wire; the outside was connected with the electrometer and then charged. The wire was then withdrawn from the inside, and the stem was sealed at E. On March 20th B D was again insulated and connected with the electrometer; the stem was broken at E, and the inside put to earth as before. The original charge was 2170. At the end of a week the charge was found to be 1952. The week's loss was 218, or 10 per cent.

The jar was again sealed on March 20th with a charge of 1875. On April 7th the charge was 1332; so that the loss in 18 days was 543, or 28 per cent. of the whole charge.

On Jan. 5th, 1875, the author gave a charge of 1465 to a flint-glass jar. On March 16th the electricity had all disappeared. Another flint-glass jar charged to 1048 on Jan. 5th, when opened on March 16th had a charge of 144, the loss in 70 days being 904, or 86 per cent.

flint-glass jars, of the shape shown in fig. 1, are now being made. The composition of the glass of each jar is known to be the same, and glass of the same composition as that of any of the jars is readily to be obtained. The diameter of the bulbs is 1.5 ins. and their thickness about 0.25 centim. A jar is filled with water to the top of the stem. A wet cloth covering all parts of the stem below the level of the insulator forms an outside jacket. After being sealed, the jars are placed in running water, the temperature of which is never greater than 50° F., nor less than 46° F. The following observations have been made :—

- 1. Charged 994. Opened after 10 days. No charge remaining.
- 2. Charged 2085. Opened after 7 days 6 hours. The charge remaining was 276.
- 3. Charged 1933. Opened after 10 days. The charge remaining was 868.

The apparatus shown in fig. 2 was employed to determine the temperature and electric conductivity in a flint-glass jar. The jar was filled to the height A, at ordinary temperature, with sulphuric acid. A is a cork supporting the glass insulator C, with a wire D containing pumice moistened with sulphuric acid. A wire hangs into the sulphuric acid and terminates in a

The rapidities of loss are obtained by dividing the Napierian logarithm of the quotient of two charges or readings by the interval in minutes between the two observations. Thus it is roughly assumed that the capacity of the jar is the same at all temperatures.

*On the Electric Conductivity of Glass.* [June 10,

on which occurs after charging is very marked. Some series of results seem to indicate an increased polarization with temperature. Thus, when at any low temperature the charge calculated from successive intervals is nearly constant, if the temperature is rapidly raised and then kept constant, the conductivity diminishes for a short time as if the jar were recharged.

The charge is approximately represented by

$$\frac{I AV}{4\pi a},$$

where  $I$  is the specific inductive capacity of the glass,  $V$  the reading of the electrometer, and  $a$  the thickness of the glass. But if  $k$  is the specific conductivity of the glass, the rate of conduction through it is

$$kA \frac{V}{a},$$

which, when conducted through, divided by the charge, is equal to

$$\frac{4\pi k}{I}.$$

$$= \frac{1}{4\pi} \cdot \frac{\text{difference of Napierian logarithms}}{\text{difference of times}},$$

which, when multiplied by the specific inductive capacity of loss given above multiplied by the specific inductive

## VIII. "Effects of Stress on Inductive Magnetism in Soft Iron."

(Preliminary Notice.) By Prof. Sir WILLIAM THOMSON,  
F.R.S. Received June 10, 1875.

1. At the last ordinary meeting of the Royal Society (May 27), after fully describing experiments by which I had found certain remarkable effects of stress on inductive and retained magnetism in steel and soft iron, I briefly referred to seeming anomalies presented by soft iron which had much perplexed me since the 23rd of December. Differences presented by the different specimens of soft-iron wire which I tried complicated the question very much; but one of them, the softest of all, a wire specially made by Messrs. Richard Johnson and Nephew, of Manchester, for this investigation, through the kindness of Mr. William H. Johnson, gave a result standing clearly out from the general confusion, and pointing the way to further experiments, by which, within the fortnight which has intervened since my former communication, I have arrived at a complete explanation of all that had formerly seemed anomalous. These experiments have been performed in the Physical Laboratory of the University of Glasgow by Mr. Andrew Gray and Mr. Thomas Gray, according to instructions which, in my absence, I have sent them from day to day by post and telegraph.

2. The guiding result (described near the end of my former paper, and referred to in the last paragraph but one of the Abstract in Proceedings of the Royal Society for May 27) was, that the softest wire, tried with weights on and off repeatedly, after it had been magnetized in either direction by making the current, in the positive or negative direction, and stopping it, gave effects on the ballistic galvanometer which proved a shaking out of residual magnetism by the first two or three ons and offs, and a gradual settlement into a condition in which the effect of "on" was an *augmentation*, and the effect of "off" a diminution, of the inductive magnetization due to the vertical component of the earth's magnetizing force. When a fresh piece of the same wire was put into the apparatus and tested with weights on and off it gave this same effect. If the wire had been turned upper end down and tried again in the course of any of the experiments, still this same effect would have been shown. It seemed perfectly clear that in these experiments there was no other efficient dipolar quality of the apparatus by which the positive throw of the ballistic galvanometer could be given by putting on the weight, and the negative throw by taking it off, than the vertical component of the earth's magnetic force.

3. Yet I did not consider that I had *explained* the result by the terrestrial influence, because, for *all* the specimens of steel and soft iron, the effect of weights on had been uniformly to *diminish*, and of weights off to *augment* the magnetism when the magnetizing current was kept flowing. And I was, moreover, perplexed by the magnitude of the

Prof. Sir W. Thomson on the Effects of [June 10,

of weights on and off shown by the very soft iron wire, feeble magnetizing influence of the earth, being many (five times to nine or ten times) as great as the effects which are produced in the same wires when under the magnetizing forces of the currents through the helix. By reducing the strength of the magnetizing current gradually, the small positive effect of the "on" with the positive current and the small negative effect with the negative current are brought to approximate more and more nearly to the effect of the "on" when there is no current at all. Immediately former communication I therefore arranged to have made with different measured strengths of current, feebler and the law of the continuity thus pointed out should be so speedily arrived at the following astonishing conclu-

the magnetizing force does not exceed a certain critical value the effects of *pull* and *relaxation* are respectively to augment the induced magnetization.

the magnetizing force exceeds the critical value the *pull* diminishes, *relaxation* augments, the induced magneti-

critical value of the magnetizing force for the annealed wire with 14 lbs. on and off is about 17 or 18, if (for

de to-day for the purpose of finding accurately the amount of current which, by neutralizing the vertical force of the earth, gives an accurate zero effect for the "off" and "on." The elongation of the curve through the plus's, to cut the line on its negative side, is ideal, and is inserted to illustrate the relation of the curve to the other. By the two curves cutting the line at  $+8$  and  $-8$ , we see that 8 is the strength of the current, on the scale of the battery-galvanometer, which gives a magnetic force of the helix equal to the vertical component of the terrestrial force.

A series of experiments to test the inductive effects of changing the current always in one direction, and stopping it, with a weight of 14 lbs. always on, and again with the weight off, and with various degrees of current, feebler than those used in the earlier experiments. The results with all the different intensities of magnetizing current were the same in kind as that which I found on the other experiment, operating with a much stronger magnetizing force on a wire tried; that is to say (contrarily to what I had found elsewhere), *the change of magnetization produced by repeated applications of the magnetizing force of the helix was greater with the current on.*

"On the Liquation, Fusibility, and Density of certain Alloys of Silver and Copper." By W. CHANDLER ROBERTS, Chemist of the Mint. Communicated by Dr. PERCY, F.R.S. Received March 11, 1875\*.

Alloys of silver and copper possess many curious chemical and physical properties which make them interesting apart from their economic value, and entitle them to careful investigation. The most remarkable of these is a molecular mobility, in virtue of which certain combinations of the constituents of a molten alloy become segregated from the mass, the homogeneous character of which is thereby destroyed.

These irregularities of composition have long been known. Some observations of Lazarus Erckern, in a work published in the seventeenth century†, show that he was familiar with them; that Jars possessed more accurate information on the subject is proved by his stating explicitly, in a memoir published in 1781‡, that in ingots of silver-copper alloys containing much of the base metal, the centre of the mass is less rich than the external portions.

\* Read March 18, 1875. See *ante*, p. 349.

† His work was translated in 1686 by Sir John Pettus. See 'Fleta Minor,' Book I. p. 62.

Mr. W. C. Roberts on

on question have, during the present century, been the excellent researches in this country and on the continent, systematic experiments being those of D'Arcet, Inspecteur des Monnaies at the French Mint, who in 1824 investigated the circumstances which attend the cooling of molten mixtures of silver and copper. He does not appear to have published his results; but in 1852 he published a well-known memoir\*, that the object D'Arcet had in view was the discovery of a method of rendering homogeneous the bars of silver for coinage. He adds that the researches in this direction have been in respect of obtaining such a result. I shall presently show, from the results of my experiments, that this conclusion may now be

from my own experiments, cast the alloy to be examined either in a cylindrical mould of 45 millims. dia. or in a sphere 50 millims. in dia. He concluded that the only homogeneous alloy contains 750 parts of silver and 250 of copper in 1000; and he considers the definite combination of the two metals, having the formula  $\text{Cu}_2\text{Ag}_3$  (if 63.3 be taken to be the equivalent of copper). He views the alloys of silver and copper as mixtures of this definite combination of the two metals.

Dr. W. C. Roberts studied these alloys with the minute accuracy and skill which he has shown in all his work, and he described them as "mechanical

of silver; otherwise we should expect a straight line from the alloy containing 72 per cent. of silver to that which contains only 10 per cent.

I now proceed to give the results of my own experiments.

In commencing the inquiry, it seemed probable that, by determining the melting-points of a series of the alloys of silver and copper, information of much interest might be gained as to the arrangement which attends the solidification of a fluid mass of these metals. I adopted a modification of the plan described by Pouillet\*, and employed by him in determining the specific heat of platinum at high temperatures.

As soon as the alloy under examination was melted, a wrought-iron cylinder of known weight was dropped into it by means of a wire support. The crucible was then removed from the furnace, and, when the alloy showed signs of solidifying, the iron was transferred to a calorimeter, which consisted of two concentric vessels of thin polished brass, such as is ordinarily used for determining specific heats by the method of mixtures.

It was necessary to determine the mean specific heat of the iron employed, between  $0^{\circ}\text{C}$ . and a known fixed point near the maximum temperature likely to be attained in the course of the experiments. The melting-point of silver was a convenient one, and it has been accurately ascertained by M. Becquerel†, who placed a wire of pure silver in a crucible which was enclosed in a porcelain tube surrounded by the vapour of boiling zinc, the temperature of which has been fixed by M. Deville at  $1040^{\circ}\text{C}$ .‡ As the heat was sufficient to partially fuse the silver, this temperature may safely be taken as the melting-point of the metal.

In order, therefore, to determine the specific heat of the iron, I plunged the cylinder into molten silver, and transferred it to the calorimeter. I may here observe that the film of oxide which formed on the surface of the iron to a great extent protected it from being attacked by the molten alloy; but it was impossible to avoid carrying into the calorimeter a small quantity of metal which adhered to the iron. The metal so introduced was always collected and allowed for. With pure silver 0.05701 was taken as the specific heat, while in the case of alloys the necessary correction was made by deducing the specific heat of each alloy from the specific heats of its constituents; and the equivalent weight of iron was calculated by multiplying the weight of introduced metal by its specific heat, and dividing this product by the specific heat of iron as ascertained by preliminary experiments. This weight was then added to that of the iron employed.

The specific heats of metals at high temperatures have not been deter-

adoption of Regnault's numbers in calculating the heat calorimeter by the alloys may tend to make the results a high.

of the experiments were calculated by means of the following:—

$$x = \frac{(P + p_1 c_1 + p_2 c_2)(\Theta - t)}{p(T - \Theta)},$$

weight of the iron employed.

" water.

$p_1 c_1$  are the water-equivalents of the calorimeter and thermometer respectively.

initial temperature of the iron.

" " " water.

final "

specific heat required.

iniment these quantities had the following values:—

= 83.140 grms.

$T = 1040^\circ \text{C.}$

= 260.520 "

$t = 16^\circ \text{C.}$

= 15.687 "

$\Theta = 63^\circ \text{C.}$

of silver carried over was 3.266 grms., the heating effect

of heat sustained by the iron during its transfer from the crucible to the calorimeter; and (4) the radiation from this instrument.

The melting-point of copper has not been exactly ascertained; and I experienced great difficulty in determining it by means of the calorimeter, as the molten metal adheres tenaciously to the iron. Accuracy on this point is not absolutely essential to this inquiry, and I therefore adopted  $1330^{\circ}\text{C.}$ , as this is considered by Dr. Van Riemsdijk\* to be the probable melting-point of pure copper.

The several alloys were synthetically prepared by melting together pure silver and pure copper; and as soon as the crucible containing the fused metal was withdrawn from the furnace, a small portion of the thoroughly stirred alloy was granulated and set aside for analysis.

The requisite data for ascertaining the melting-point of each alloy were furnished by an experiment similar to that which was made for determining the specific heat of the iron, and in calculating the result it was only necessary to transpose the equation already given,  $T$  being the unknown quantity instead of  $x$ . The formula then becomes

$$T = \frac{(P + p, c. + p_{ii} c_{ii})(\Theta - t)}{p x} + \Theta,$$

the value assigned to  $x$  being in all cases 0.15693, the mean specific heat of iron, as given above.

To take an example. In one experiment to determine the melting-point of the 820.7 alloy, the following values were obtained:—

$$\begin{array}{ll} P & = 247.74 \text{ grms.} & t & = 15^{\circ} \text{ C.} \\ p, c. + p_{ii} c_{ii} & = 15.687 \text{ „} & \Theta & = 56^{\circ} \text{ C.} \\ p & = 82.55 \text{ „} \end{array}$$

The weight of alloy carried over was 3.608 grms., the heating effect of which was equivalent to that of 1.543 gm. of iron. Therefore the corrected value of  $p$  is

$$82.55 + 1.543 \text{ gm.} = 84.093 \text{ grms.}$$

Substituting these values in the above equation,

$$\begin{aligned} T &= \frac{(247.74 + 15.687)(56 - 15)}{84.093 \times 0.15693} + 56 \\ &= 874^{\circ}.42 \text{ C.} \end{aligned}$$

The results of the experiments are given in the following Table:—

\* Archives Néerlandaises, t. iii. (1868).

17.	0 (pure copper).	...	...	1330

These melting-points are graphically represented by the accompanying curve (next page); the coordinates are the amounts of silver in the several alloys and their melting-points.

It will be observed that the curve exhibits a somewhat rapid decrement from pure silver to the alloy which contains 925 parts of silver, the one employed for the British silver coins. In it the relation between the amounts of metals present is approximately represented by the formula  $\text{Ag}_2\text{Cu}$ .

The alloys numbered 7 and 8 are of singular interest. The first, which contains 718.93 parts of silver, is Levol's homogeneous alloy; and I anticipated that it would have the lowest melting-point; but the results showed that the alloy containing 630.29 parts of silver (No. 8) melts at a point which is 23.7 degrees lower. In this alloy a very simple relation exists between the atoms of the constituent metals, the formula being  $\text{AgCu}$ . Additional interest is imparted to it by Matthiessen's curve of electric conductivity having shown that the arrangement of an alloy of this composition would probably be peculiar. From this point the curve passes through the points representing alloys in which base metal predominates to 1330° C., the melting-point of pure copper.

Further evidence as to the melting-points of Nos. 7 and 8 was afforded by placing strips of them in small covered crucibles surrounded by the vapour of boiling cadmium, the temperature of which has been fixed by Deville at 860° C. Both alloys melted, the first partially, the second completely. I am convinced, therefore, that the melting-points of the alloys generally are not inaccurately indicated by the curve. It is, however, not improbable that the examination of a more extended series of alloys may

## MELTING-POINTS OF SILVER-COPPER ALLOYS.

Parts of Silver in 1000 parts of Alloy.

point to the necessity of slightly modifying its form. This critical examination is especially necessary in the region of the 497 alloy; for not only do the results obtained on it diverge widely among themselves, but their mean is far removed from the probable line of the curve.

I am not satisfied with the results I have obtained on an alloy which contains 773.2 parts of silver. This alloy is of special interest; its formula is  $\text{Ag}_2\text{Cu}$ , silver being monatomic.

[Since the above was submitted to the Royal Society, I have made additional experiments on alloys in these two portions of the curve. The calorimeter used was of thin polished silver, capable of holding 1200 grammes of water, which were never raised through more than  $15^\circ\text{C}$ . The water-equivalent of the instrument was only 15.72 grammes. The masses of iron used were such as had been employed as carriers of heat in the first experiments: the mean of several very concordant results gave .15003 as the specific heat of the iron when this new calorimeter is employed; and, as has already been pointed out (p. 484), this number includes and neutralizes several errors.

The results are distinguished by an asterisk in the Table, and have been added to those originally indicated in the Diagram. They confirm the direction originally given to the curve in the region of the alloys which contain from 718 to 800 parts of silver; but the existence of a cusp has been detected at the point which represents the alloy No. 11 ( $\text{Ag}_2\text{Cu}$ ). It may be interesting to point out that the results from which Matthiessen's curve of electric conductivity was developed appear to prove the presence of a cusp at the point which represents the alloy 459.4 ( $\text{AgCu}$ ).—15th May, 1875.]

It may be useful to compare these results with those obtained by Rudberg on alloys of lead and tin. He found that when a thermometer is placed in a molten alloy of these metals two distinct stationary points are indicated during the passage from the liquid to the solid state. One of these points is always  $187^\circ\text{C}$ .; and in the alloy  $\text{PbSn}$ , the two points coincide at this temperature—a fact which led Rudberg to conclude that it was the only alloy in which the whole of the metals were chemically combined. I hope, in continuing this inquiry, to be able to ascertain whether the change of state in the case of silver-copper alloys also terminates at a constant temperature. I may mention that M. A. Rich\* determined the melting-points of certain alloys of tin and copper by means of Becquerel's thermo-electric pyrometer; and he obtained concordant results with the alloys  $\text{SnCu}$ , and  $\text{SnCu}_2$ ; but with all other alloys the results differed widely among themselves.

It is at present difficult to show the direct bearing of these results on the phenomena of liquation in alloys of silver and copper; but the curve is valuable, as it proves that the alloys Nos. 7 and 8 occupy positions in

represented on pp. 490 & 491 were cast in moulds of this  
the first of these (fig. 1), the composition of which was about  
ver per 1000 of the alloy, was cooled rapidly. Its structure  
s general conclusion, as the centre contains 12·8 parts per  
silver than the external portions. On the other hand,  
at when the same alloy is slowly cooled the constituents  
any molecular re-arrangement, the maximum difference  
per thousand. A cube of the alloy used for the French  
rapidly cooled, exhibits a difference of 10·1 parts per

silver. Fig. 6 shows the results of analyses on the different portions of a mass of the alloy containing 333·3 parts of silver per thousand ( $\text{Ag Cu}_4$ ). The mass varies in composition, but the arrangement does not appear to have been guided by any law.

The inquiry appears to show that several alloys of silver and copper are, under suitable conditions, as homogeneous as Levot's alloy, the chief peculiarity of which consists in its not being liable to liquation when poured into a mould at the ordinary temperature and cooled rapidly.

It will be remembered that experiments prove that in all alloys which contain less than 71·89 per cent. of silver the external parts are richer than the centre. The curve of fusibility shows that the alloys which contain less than 35 per cent. of silver have higher melting-points than other alloys of silver and copper, or even than pure silver. It would not appear, therefore, that liquation is the falling out of the least fusible alloy present in a mass of silver and copper; for if it were, the external portions of the alloys would in all cases be less rich in silver than the centre.

I cannot at this stage of the inquiry offer a complete explanation of this molecular rearrangement; but I venture to think that the results already obtained are interesting. They show, first, that the same alloys are situated on the turning-points of the curves of fusibility and electric conductivity; and second, that the arrangement of an alloy is to a great extent dependent on the rate at which it is cooled.

In accordance with a suggestion made to me by Mr. R. Mallet, I have endeavoured to determine the relation between the densities of silver in the solid and the molten state. I adopted the method which he devised and has employed in the determination of the density of molten cast iron\*.

A conical vessel of best thin Low-Moor plate (1 millim. thick), about 16 centims. in height, and having an internal volume of about 540 cub. centims., was weighed, first empty, and subsequently when filled with distilled water at a known temperature. The necessary data were thus afforded for accurately determining its capacity at the temperature of the air. Molten silver was then poured into it, the temperature at the time of pouring being ascertained by the calorimetric method already described. The precautions, as regards filling, pointed out by Mr. Mallet were adopted; and as soon as the metal was quite cold, the cone with its contents was again weighed.

The surface of the molten metal in the crucible was covered with charcoal; and as pure silver, when in a liquid state, is known to absorb oxygen if exposed to the air, the cone was filled with an atmosphere of coal-gas.

\* Proc. Roy. Soc. vol. xxii. p. 366, and vol. xxiii. p. 209.

Mr. W. C. Roberts on

important of the corrections applied to these results was that volume of the iron vessel which attended the introduction of metal.

Qualities of wrought iron vary considerably as to dilatation. As a fact, together with the known increase in the expansion at high temperatures, rendered it necessary to determine the mean coefficient of expansion at 0° C. and the melting-point of silver. For this purpose a modification of Ramsden's method was adopted, the iron being placed in a bath of molten silver and surrounded by molten silver. The micrometer-measurements were taken when the length of the iron remained for a short time constant, as this was the true solidifying-point of the silver, the latent heat of liquefaction rendering the temperature constant.

A number of experiments were made; and although they were attended with much difficulty, I believe the following results to be trustworthy. The numbers represent the mean coefficient of linear expansion of the Low-Moor iron employed, up to the temperature of the melting-point of silver (er) :—

•00001242,  
•00001254,  
•00001215,  
•00001219,

The mean of the coefficients of linear dilatation of silver between 0° and 100° C., given by various authorities, is

0.00002015.

It will thus be seen that the expansion of silver between 0° C. and 1050° C. is about twice as much as it would have been had this rate of expansion been maintained through the whole range of temperature.

The mean coefficient of linear dilatation of Levöl's alloy, as deduced from the results given in the Table, is

0.00003703 ;

but it is impossible to compare this with the rate of expansion at low temperatures, as the latter has not been ascertained.

WALTON HOOKER, C.B., President, in the Chair.

The received were laid on the table, and thanks ordered for

being introduced, one was employed for magnetizing the machine, the other being used for external work. This machine gave a good electric light &c., and was shown in the Exhibition of Paris, 1867, when a silver medal was awarded for it.

To simplify this machine, the author of this paper afterwards placed the two armatures in the same groove between the poles of the electromagnet, bolting the two together at right angles to each other, so that they came under the influence of the magnetism alternately; by this method one pair of bearings was sufficient instead of two, and the machine altogether was much simplified.

The machine now about to be described is a still further modification, in which the greatest amount of simplicity and effective power are combined.

The apparatus consists essentially of an electromagnet with shoes, forming a groove in which a Siemens's armature is made to revolve: this is much the same as the original machines made by Siemens and Wheatstone; but the difference occurs in the break or commutator; here there are two springs or rubbers employed in taking the current off from the commutator. The commutator consists of three rings: one of these rings is complete for three quarters of the circle, the other quarter being cut away; another ring is cut away three quarters, leaving the one quarter; and in between these two rings is a third ring, insulated and connected with the insulated end of the wire wound round the armature; on this centre ring are projecting pieces, one a quarter of a circle and the other three quarters, so arranged as to complete the two outer circles. The rubber spring which comes into contact with the quarter of the middle circle is connected with the electromagnet of the machine, and the armature is so arranged that at the time of contact the best magnetizing current is developed. The other spring rubber is in connexion with the wire on the armature during the other three quarters of its revolution; and this is connected with any external piece of apparatus required to be worked.

By this arrangement, the alternate currents being utilized, they are all in the same direction; and by the length of contact the whole of the current is obtained in the best condition for heating wires, decomposing water, giving an electric light, and other usual experiments.

At present a model machine has been constructed on this principle, the armature of which measures 5 inches long by 2 inches diameter, on which is wound about 50 feet of cotton-covered copper wire, no. 16, B. W. G. The magnet has about 300 feet of covered copper wire, no. 14, B. W. G.: the whole instrument, without the driving-gear, weighs 26 lbs.; with this apparatus 8 inches of platinum wire, .005, can be made red-hot, water is rapidly decomposed, &c.

The armature is constructed specially to prevent the accumulation of heat to which every class of dynamo-magneto-electric machine is liable. It is

(Abstract.)

...nal form and method of growth.

...ng.

Well-marked stomata, both spuria and vera, are to be seen on the surface, the latter unquestionably forming orifices of entrance into the vast system of canals of which the proper system of the cord is composed.

The epithelium varies somewhat in its arrangements near the placenta and near the foetus.

In the former position the cells are smaller, more irregularly jointed, and apparently somewhat more elongated in the direction of the long axis of the cord than they are near the foetus.

The whole appearance of the cells gives the impression that the covering is older here; and in the canals and in the stomata are to be seen rows of minute refracting globules, visible only under very high powers, the nature of which I have been unable to make out, as they appear only after deep silver-staining.

III. The alveolated canalicular tissue of the cord is divided throughout its entire length into three columns, the divisions between which are not visible to the naked eye, but become very perceptible when one of the columns is injected by Recklinghausen's method.

When the canals are empty they present the appearance of fibrous tissue by the collapse of their walls, and when partially distended they look like stellate cells. This has led to the erroneous description of a fibrous matrix in which occur stellate cells. In the lacunar spaces of the canals the oval nuclei are imbedded.

These nuclei do not alter their shapes or positions.

In injecting this system of canals, the fluid passes more readily in the direction from the foetus to the placenta than in the reverse way.

During the process minute streams of the injection may be seen flowing from the surface of the cord; and these are not due to rents.

Transverse and longitudinal sections of the injected columns show that the canals are stellate in every plane.

In the alveoli between the canals the wandering cells are found. Silver-staining shows that these canals are walled. The nuclei are not fusiform, for when magnified 1000 diameters they are seen to be oval and provided with a very small nucleolus. The statement that they send processes into the branches of the canals is due to an optical illusion, dispelled by the use of high-power immersion lenses.

The round cells which occur in the alveoli have very large nuclei, quite disproportionate to the surrounding protoplasm.

They are not constant. In some cords, especially those removed from large children, they are found very scantily, whilst on the cord of a small eight-months' child they were found to be extremely abundant.

They are also often more numerous in some parts of the cord than in others, and in one district of the cord than in another.

They are most abundant near the umbilicus and near the capillaries. They may be seen moving on the warm stage and exhibiting amoeboid movements after having taken up litmus colour.

able to discover any nerve-fibres in the cord.

Our tissue may be demonstrated to end in three cones, the apex of each of which is just within the tendinous ring; the injection will not pass through the tendinous ring; it is needed in making it enter the capillaries of the cord from the tissue.

Injection of the capillary plexus running from the dermal tissue is successfully accomplished (and this is, for many reasons, a necessary step), there will be found a peculiar vascular arrangement in the cord, lying in the firm nucleated tissue which forms the basis of this arrangement is a peculiar sacculated excavation in the fibrous tissue, as it is doubtful if it has a spiral arrangement. It seems to have a spiral arrangement, for in one place it appears as only a screw could.

From the omphalic ring at least forty-five millims. up into the body of the cord, giving off at short intervals thick trunks which break up into capillaries.

Arteries do not form loops, but enter directly into the canal. It is possible to inject a large extent of all three distances of the cord by passing the injection through the tendinous ring seems to originate from the small arteries of the dermal wall, which enter with the vein.

There is a close analogy between this arrangement and that

The limitation of the canalicular tissue of the cord, at its placental attachment, is quite as abrupt.

The injection-fluid cannot be made to pass from the substance of the cord into the placenta, for it is arrested by a firm membrane derived from the chorion, which the vessels of the cord penetrate, and between two layers of which they lie. There is absolutely no connexion between the nutritive system of the cord and that of the placenta.

VI. The chief factor in the nutrition of the cord is the arrangement of capillaries entering it from the foetus. From the facts observed by me in cases of extra-uterine gestation, it is likely, however, that the stomata of the epithelial surfaces of the cord play an important part in its nutrition.

The liquor amnii contains substances which are very suggestive that the fluid is used for purposes of nutrition, and perhaps for the nutrition of the cord. In recent cases of extra-uterine foetation, before the liquor amnii becomes absorbed, the cord remains fresh and plump. After the fluid has been absorbed the cord becomes shrivelled; but it still retains its structural characters, minus the wandering cells. It may be, therefore, that the canalicular nuclei are able to keep the cord in repair, as it were, by the matters absorbed from the liquor amnii, until that fluid disappears—very much as ivy continues to live after its connexion with its root has been severed. Indeed the analogy between the umbilical cord and vegetable tissue is, as I hope to be able to show further, a very close one.

III. "First Report of the Naturalist accompanying the Transit-of-Venus Expedition to Kerguelen's Island in 1874." (Conclusion.) By the Rev. A. E. EATON. Communicated by the PRESIDENT. Received May 10, 1875.

In January 1875, shortly after the departure of the American Expedition from Royal Sound, an opportunity occurred of visiting another part of Kerguelen's Island. To relieve the ennui of his officers and men, who by that time were thoroughly tired of being detained without any definite occupation in an uninhabited island, Captain Fairfax ordered the 'Volage' to leave Observatory Bay, and proceeded to Swain's Bay, where he remained three weeks. During this period he entertained me as his guest, took me to the best localities in the bay for collecting, and rendered me every assistance that lay in his power. The Royal Society is therefore indebted to Captain Fairfax for a fine series of Algæ from Swain's Bay, comprising many species not found in Observatory Bay, and some that were not known to be indigenous to the island. Most of these are described in the 'Flora Antarctica' as Falkland-Islands species. Captain Fairfax at the same time enabled me to secure the skeleton of a *Globiocephalus*, which was found dead in shallow water by Mr. Forrest (Mids.). Most of the epidermis had been removed by small

at it was not possible to ascertain the colour of the animal. Mr. L. B. Aldridge, B.N., very kindly photographed the carcass before it was buried, and its dimensions were carefully taken by one of the boat's crew, so that before it will be easily identified.

Elephants were frequently found by us in Swain's Bay. They are uniformly reddish brown, others are pale, blotched with darker grey. They usually lie just above the beach in the hollows among the *Acacia* and *Azorella*, where they are sheltered from the wind. On being approached they make no attempt to escape (possibly because there are no land animals indigenous to the island capable of molesting them) to cause them to acquire a habit of raising up the fore part of their body, open the mouth wide and utter a peculiar slobbering cry. My mammalian specimens, unfortunately, are not so complete as they were when first procured, owing to the inability of preventing "liberty men" and others taking away the "great curiosities" whilst the process of cleaning them was going on. The removal of stones, purposely laid upon some of the specimens, led to the loss of the fore limbs of seals, &c., which were blown away by the wind.

Of birds, with the exception of two species (a *Procellaria* and a *Puffinus*), are represented in the Cape-Town Museum.

A *Wilsoni* (Dr. Wyville Thomson, however, seems to consider it a new species) arrived in the

of my hand. A Sheathbill, after pecking at my boots, ate in succession six eggs held out to it. But the Skua behaved in a still more extraordinary manner. On approaching within three hundred yards of the nest it was evident, from the excitement of the old birds, that the young were hatched; and on searching for the nestlings, the old birds commenced their usual onslaught when within two hundred yards of the nest. Disregarding their outcries and fierce swooping down, I soon found the young ones crouching amongst the herbage some distance apart from one another and the nest (which they leave at an early age), and sat beside the nearest. The hen Skua immediately alighted within a yard of me and continued her vociferations, whilst the cock withdrew to the other nestling. On stroking her chick the hen became more excited than ever and advanced a little nearer. Taking a Prion's egg from my pocket and holding it out, her cries ceased whilst she eyed the egg, but recommenced when she again looked at me. She once more looked at the egg, became silent, waddled cautiously up and pecked gently at my finger, then, reassured, pecked the egg, which she very soon made an end of. In the same way she ate a young Prion killed for the purpose, and afterwards flew to the hole from whence the bird had been taken to see if it contained another; and upon my digging at some other holes, she came near and stood by in eager expectancy of further gratuities. With regard to her pecking first at the finger before the egg, I would observe that wild birds usually do this previous to feeding out of the hand. The Sheathbills did the same, and so do English birds which have never been in confinement. It seems to be their way of testing the nature of any strange-looking object.

The Sheathbill was plentiful in Swain's Bay, and a fair number of their eggs were procured. As Dr. Kidder, the American Naturalist, had not succeeded in finding any, I was anxious that he should have some; but did not consider myself at liberty to give him more than one, and that a damaged specimen almost in halves. The Royal Society will now be able to be more liberal.

A fine male example of a *Raia*, differing from the species previously found in Royal Sound, was shot by Mr. Budds, the chaplain of H.M.S. 'Volage,' two days before we sailed.

The *Agrostis* mentioned when I last wrote came into flower about the third week in January. It can scarcely be said to form a sward, or pasturage even, in the neighbourhoods visited by me. The *Limosella* was found in February in fruit and flower, very sparingly, in only one shallow lake between the Observatory and Mount Crozier.

I omitted to inform you that the Kerguelen-Island *Callitriche*, given in the 'Flora Antarctica' as *C. verna* var. *terrestris*, should (I think) be regarded as a form of *C. pedunculata* rather than of *C. verna*. It has no bracts, and seems to exhibit other peculiarities of *C. pedunculata*. Prof. Wyville Thomson alludes to it as *C. verna*; but probably he

Mr. J. E. H. Gordon on the Determination [June 19]

came from the 'Flora' without suspicion, unless, indeed, (likely), both species occur on the island. For the satisfaction of botanists I have brought back specimens of the plants in flower and fruit, as well as dried examples.

Which was new to me, according to Lady Barkly, may be *Adiantum (Grammitis) australe*.

For the following particulars I am sorry to have occasion to report

that the following Lepidopterous larvæ all died before our arrival at the

larger Algae collected were spoilt. One suite of dried algae, through the box in which they were contained being exposed to the rain, by one of the servants a few days before we left, my knowing it had been moved from its place. The box, which I gathered the day before we left the island, was sent on board with directions that the box should be placed in an accessible place. Unfortunately the message miscarried, the box was stowed away and I could not get at it until a fortnight afterwards, when the whole of its contents were completely decomposed.

Some of examples of some of the flowering plants were lost through the difficulty of attending to them when collected.

Left St. Helen's Island in H.M.S. 'Supply' on the 27th February, arrived at St. John's Bay on the 31st March, and at Gravesend on the

units for a standard substance. Distilled water was used, and the magnetic force was produced by means of an electric current in a helix, as the magnetism of iron magnets is an undetermined function of the shape and nature of the iron core.

The strength of the helix was determined by comparing the magnetic force at a series of seven equidistant points along its axis in terms of that at the centre of the great dynamometer of the British Association, whose power is known in absolute measure.

The intensities were compared by varying currents sent opposite ways through each, till the action on a small magnet at their common centre was nil.

The intensity at each of a series of points being known for a given current, the difference of magnetic potential at the two ends for that current was obtained by integrating with respect to the length between limits corresponding to the end of the helix.

For this Weddle's rule was used, viz.

$$\int_0^6 u_x dx = \frac{3}{10} h \{u_0 + u_1 + u_2 + u_3 + 5(u_4 + u_5) + 6u_6\},$$

where  $6^h$  is the length of the helix and  $u_x$  the magnetic intensity at any point.

The difference of magnetic potential at the ends for a certain current being known, the strength,  $N$ , of the helix (which is the ratio of this difference to the current, or the difference of magnetic potential which would be due to a unit current) is known, and is a *number*, because current and magnetic potential are of the same dimensions.

In the helix used, which was about 26.34 centims. in length and 13 centims. in diameter, we had

$$N = 10752.$$

The absolute value of the degrees of a tangent galvanometer was also determined by placing it under the dynamometer.

To determine the rotation of the plane of polarization, a Nicol's prism, set in a circle, was used, and the light was polarized by means of a prism invented by Professor Jellett, and described by him in vol. xxv. of the Transactions of the Royal Irish Academy.

It was constructed of Iceland spar, and its field of vision consisted of a circle divided by a line, the light of one half of which was polarized in a certain plane, and the light of the other half in a plane inclined at about  $2^\circ$  to that of the first. The intermediate position of the Nicol, when the whole field was equally dark, could be determined with some accuracy.

The water was contained in a tube with glass ends, of the same length as the helix, and placed with it. The polarized ray was sent through it,

t, whose intensity,  $C$ , was measured by the tangent galvanometer, was sent through the helix first in one direction, then in the other, and the plane of polarization observed. The difference of the readings was the rotation produced by the current.

Let  $\theta$  this rotation expressed in circular measure, and define  $\omega$  as the rotation which a unit current in a unit coil produces in unit of length of distilled water, we have

$$\omega = \frac{\theta}{NC}.$$

One of the series of experiments made was to obtain for  $\omega$  the value

$$\omega = (10^{-7}) 4.49 \text{ centimetre-gramme-seconds.}$$

The dimensions obviously are the reciprocal of those of current, viz.

$$[\omega] = [L^{-\frac{1}{2}} M^{-\frac{1}{2}} T].$$

In our result in a slightly different form we may say that, if plane polarized light passes through distilled water, and the magnetic field of the water at any two points in the path of the ray is reversed, then the plane of polarization will be rotated between the two points by  $\frac{1}{10}$  ten-millionths of a unit of circular measure.

lateral extension in the latter, so that in passing from one point to another the roller does in truth pass over a greater extent of surface than the distance between these points. A simple experiment was sufficient to verify the truth of this conclusion. An iron roller 18 inches in circumference was found to roll through something like  $\frac{3}{4}$  inch less than a yard in two complete revolutions when rolling on a plate of india-rubber. The softness of the india-rubber suffered the roller to indent it considerably ; and hence it might be expected that the effect would be much more apparent than when the roller was rolling on iron or any hard material. At the same time there is doubtless a certain amount of indentation in this latter case ; and this will probably cause a similar alteration in the distance rolled through, although too small to allow its being measured.

This falling off from what may be called the geometrical distance, suggested an explanation of the resistance to rolling, namely, that the extension of the surface or surfaces at the point of contact causes the one surface to slide over the other ; and this sliding is accomplished against friction. In this way we should expect to find the resistance to rolling greatest under those circumstances in which the sliding is greatest, *i. e.* where the indentation is greatest ; and so far it is in accordance with Coulomb's laws. In the case of india-rubber, we find the slipping is very large ; and hence we should expect the resistance to rolling to be large also ; and accordingly we find it so, for it is more than ten times as great as when the roller is on an iron plane. This very great resistance which india-rubber causes to rolling appears not to have previously caught attention ; and yet it is the natural explanation of the invariable failure which has attended the numerous endeavours which have been made to use this material for the tires of wheels.

This idea, that the resistance to rolling is due to the friction between the surfaces sliding at the point of contact, naturally leads to the conclusion that it must depend on the coefficient of friction between these surfaces, and that we might expect to diminish the resistance by using oil or any other means of reducing the coefficient of friction. This was the author's first impression. Experiments, however, showed that the effect of oiling the surface, although it did generally reduce the resistance, was very small ; and sometimes it appeared to act in the reverse manner, and increase the resistance. This conclusion or surmise was therefore wrong ; and the cause of the error was not far to seek. It consisted in having overlooked the fact that friction not only opposes the sliding of the one surface over the other, but also prevents it to a considerable extent, and thus modifies the deformation which would otherwise take place ; so that any diminution in the coefficient of friction is attended with an increase in the extent of slipping, which tends to balance the advantage gained by the reduced coefficient.

The truth of this view derives independent support from a circumstance remotely connected with rolling-friction, of which it furnishes an

Prof. O. Reynolds on *Rolling-Friction*.

[June 17,

When the roller rests on a horizontal surface and is very hard, it does not move off, but oscillates backwards and forwards on all kinds of elastic surfaces; on soft india-rubber oscillations are both large and continue for some time. Now if the deformation in the surface of the rubber were complete, there would be no tendency to bring the roller back; but since, owing to friction, the surface under the advancing side of the roller, is prevented from contracting, while that under the other side is prevented from contracting, the surface is in a state of constraint from which the surface is endeavored to free itself by forcing the roller back.

The relative softness of the materials, the curvature of the roller, and the lateral extension both of the roller and the plane at the point of contact, so that if the roller and the plane were of the same material, it would still be slipping. This would not be the case, however, if two wheels of the same diameter and material rolling in

In the short sketch of the subject of the paper, a considerable part was devoted to the examination and illustration of the exact nature of the deformation at the point of contact occurs, and the influence of friction upon it. The latter part of the paper contains an account of numerous experiments, and their results, which were under consideration of this investigation.

mediately expanding to the same volume as it previously occupied, and the viscosity of the material, which also renders it slow to expand. Both these causes are, however, rather connected with the effect of the speed of the roller on the resistance than with the residual resistance, which, so far as the surfaces are perfectly true and perfectly hard, appears to be due to the friction which accompanies the deformation, and is hence called *rolling-friction*.

No attempt has yet been made to investigate the laws of rolling-friction, although the author hopes to continue the investigation in this direction as soon as he has obtained the necessary apparatus.

At the end of the paper attention is called to certain phenomena connected with railway-wheels, which it is thought now, for the first time, receive an explanation. Thus the surprising superiority of steel rails over iron in point of durability is explained as being due as much to the fact that their hardness prevents the wearing-action, *i. e.* the slipping, as that it enables them better to withstand the wear. Also the slipping beneath the wheel explains the wear of the rails in places where brakes are not applied; and the severe lateral extension beneath the wheel is thought to explain the scaling of wrought-iron rails.

VI. "On Multiple Contact of Surfaces." By WILLIAM SPOTTISWOODE, M.A., Treas. R.S. Received May 24, 1875.

(Abstract.)

In a paper "On the Contact of Quadrics with other Surfaces," published in the Proceedings of the London Mathematical Society (May 14, 1874, p. 70), I have shown that it is not in general possible to draw a quadric surface  $V$  so as to touch a given surface  $U$  in more than two points, but that a condition must be fulfilled for every additional point. The equations expressing these conditions, being interpreted in one way, show that two points being taken arbitrarily, the third point of contact, if such there be, must lie on a curve, the equation whereof is there given. The same formulæ, interpreted in another way, serve to determine the conditions which the coefficients of the surface  $V$  must fulfil in order that the contact may be possible for three or more points taken arbitrarily upon it; and, in particular, the degrees of these conditions give the number of surfaces of different kinds which satisfy the problem.

In another paper, "Sur les Surfaces Osculatrices" (Comptes Rendus, 6 Juillet, 1874, p. 24), the corresponding conditions for the osculation of a quadric with a given surface are discussed.

In the present paper I have regarded the question in a more general way; and having shown how the formulæ for higher degrees of contact

*Non-linear Partial Differential Equations.* [June 17,

I have developed more in detail some special cases of

for the convenience of the reader, I have in § 1 briefly recapitulated parts of the two papers above quoted. In § 2 I have given, as a first sketch of a general theory of multiple contact with surfaces, § 3 the particular cases of three-, four-, five-, and six-point contact are discussed; and in § 4 some conditions for the existence of four-, five-, six-pointic single (i. e. not multiple) contact are given.

The investigation concerns the contact of quadrics only with surfaces. The concluding part of the paper is concerned with the problem for cubics, in which case conditions of possibility for simple or two-pointic contact, but are first met with for surfaces. The conditions in question, with some of their consequences are here given; and their complexity will perhaps be a justification for not pursuing the subject further in this paper.

VIII. "Reduction of Anemograms taken at Armagh Observatory in the Years 1857 to 1863." By T. R. ROBINSON, D.D., F.R.S., &c. Received June 11, 1875.

The instrument with which these observations were made is described in the Transactions of the Royal Irish Academy, vol. xxii., and a continuous series of its records exist from 1845 to 1870. With the limited resources of this Observatory it was not in my power to reduce them; but it seemed to some distinguished members of the Royal Society desirable to ascertain whether such observations are competent to develop any laws amid the seeming lawlessness of the winds, and they obtained for me a grant from the Government Fund to discuss the anemograms of these seven years. Unfortunately the work has been long delayed by various accidents.

Of the causes of wind some are undoubtedly periodical; and though they are masked by others of greater magnitude, which, in the present state of our knowledge, seem quite lawless, yet these will disappear from the mean of a sufficient number of observations and leave as residual the first. Of the periodical causes the unequal distribution of heat is the most important; and this, depending on the place of the sun, is evidently a function of the time.

The immediate data of the anemograms, the velocity and direction of the wind, though not the most convenient for combining in great numbers, yet are those which interest most directly the general inquirer; and I have presented them in a Table, which shows for each month of the seven years the mean velocity of the wind in each octant, the number of hours during which it has blown, the maximum in each month, the number of hours above 25 miles, and the number during which the record = 0. The most striking fact shown by this Table is its extreme irregularity, not merely from octant to octant or month to month, but from year to year. Both velocity and hours are a maximum in the octant S.S.W., a minimum in N.N.E., their products being as 6:1. As to monthly variations, the amount of wind is a maximum in January, decreasing to July in the ratio of  $2\frac{1}{4} : 1$ , and thence increasing to the end of the year, with an exception in the case of March, which is greater than February as 1.13:1. This, however, does not establish the common idea of equinoctial gales; for the hours above 25 miles are fewer in March than in February, and there is no excess in September above October. There is also no clear indication of any influence of the solar spots; but for detecting this several decennial periods will be necessary. The annual variations are equally notable. The maximum velocity ranges from 71 in 1861 to 19 in 1860. If the mean velocity for each month be taken without reference to direction, it is 13.51 for January, 4.24 for June, and that for the whole year is 9.73. A mode of discussion which seems more likely to give definite laws is to resolve each velocity into a southern

and a western W, to deduce from these interpolation for-  
g periodic functions of the time for periods of one or more  
in the changes of these functions in successive periods to  
neral laws. At first sight this might seem impracticable,  
cessive discordance of the values for the same in different  
in the first term of the set, January 1<sup>st</sup> 0<sup>h</sup>, the extreme  
the seven years is, for W 20.89, for S 25.35. Evidently  
were out of the question, and even the mean for the seven  
evident from examining their probable errors. However, I  
our for the seven years, then combined these in periods of ten  
ntely took their mean for the entire month. These monthly  
en in Table III., from which it appears, first, that all the  
s of W and S are positive. This arises from the pre-  
positive over negative values; but the latter occur so fre-  
they evidently belong to the wind system; and I was at first  
ean and develop them separately. I tried it for January  
saw that in the present state of our knowledge it would  
in January the negative values are 0.27 of the whole, in  
and they are found in the septennial means of almost every  
regularly distributed that it would be almost impossible to  
in terms of the time. Even were this done, we could  
any particular instance the negative and positive results

A Table whose data belong to dates separated by considerable intervals will not give the components generally without interpolation. The formula universally adopted for this when the quantities concerned are periodic functions of the time-angle is that given by Bessel—

$$U = K + A \cos \theta + B \cos 2\theta \text{ \&c.}, + O \sin \theta + P \sin 2\theta \text{ \&c.},$$

or its secondary equivalent—

$$U = K + K' \sin (\kappa + \theta) + K'' \sin (\kappa + 2\theta) + \text{ \&c.},$$

where  $\theta$  is the hour-angle from midnight. But as the monthly variations must also be represented, the coefficients of the first equation must be developed in terms of  $\phi$  (the time-angle from the beginning of the year), and the expression of each of them multiplied by the corresponding cosine or sine of  $\theta$ . Bessel's computation of the coefficients may be much shortened where, as in the cases before us, the circle is divided into  $2n$  equal parts ( $n$  being an integer), and the first term of the series  $= 0$  or  $\frac{\pi}{2n}$ ; for, in consequence of the numerical equality of the cosine and sine of  $\theta$ ,  $180 + \theta$ ,  $180 - \theta$ , and  $360 - \theta$ , it is only necessary to compute for the first quadrant. For the horary sets this labour might be shortened by combining them in groups of 3; and the formula for this is given, but it is not quite as exact as the ordinary one, which is also given. The horary constants for  $W$  and  $S$ , computed by this last, are given in Tables V. and VI. for each month to the fourth order, and an estimate of their precision.

These constants are then developed in month-time, for which the formula is given. This, however, requires a correction; it supposes each  $u$  from which it is deduced to belong to a series of  $\phi$  in arithmetical progression. This is not the case: first, the mean of each month does not represent the  $u$  belonging to the middle of that month; secondly, the angular distances of the middle of each month from the beginning of the year are not in arithmetical progression. These are both corrected by multiplying the constants by certain factors. The secondary constants so corrected are given in Table VIII. to the 6th order.

As an example of the mode of trying what effect any periodical agent may have on the coordinates, the sun's altitude at Armagh is considered. It is developed in terms of  $\theta$ , and may probably account for 0.27 of the variation of  $W$  and 0.53 of that of  $S$ .

The paper concludes with an attempt to show from these observations the existence of an aerial tide-current, which, according to Laplace, is at its maximum 0.195 mile per hour. There was little hope of detecting so small a quantity; but the attempt would at least show how far the mean of a large number of observations may approach the truth. When the moon is east of the meridian its attraction increases  $W$ , when west

inary Notice of further Researches on the Physical  
es of Matter in the Liquid and Gaseous States under  
onditions of Pressure and Temperature." By Dr.  
s, F.R.S., Vice-President of Queen's College, Belfast.  
June 17, 1875.

ation to which this note refers has occupied me, with little  
nce my former communication in 1869 to the Society, "On  
f the Liquid and Gaseous States of Matter." It was un-

under melted lard. In this way the air enclosed within the pores of the leather is removed without the use of water, and a packing is obtained so perfect that it appears, as far as my experience goes, never to fail, provided it is used in a vessel filled with water. It is remarkable, however, that the same packing, when an apparatus specially constructed for the purpose of forged iron was filled with mercury, always yielded, even at a pressure of 40 atmospheres, in the course of a few days.

It is with regret that I am still obliged to give the pressures in atmospheres as indicated by an air- or hydrogen-manometer, without attempting for the present to apply the corrections required to reduce them to true pressures. The only satisfactory method of obtaining these corrections would be to compare the indications of the manometer with those of a column of mercury of the requisite length; and this method, as is known, was employed by Arago and Dulong, and afterwards in his classical researches by Regnault, for pressures reaching nearly to 30 atmospheres. For this moderate pressure a column of mercury about 23 metres, or 75 feet, in length had to be employed. For pressures corresponding to 500 atmospheres, at which I have no difficulty in working with my apparatus, a mercurial column of the enormous height of 380 metres, or 1250 feet, would be required. Although the mechanical difficulties in the construction of a long tube for this purpose are perhaps not insuperable, it could only be mounted in front of some rare mountain escarpment, where it would be practically impossible to conduct a long series of delicate experiments. About three years ago I had the honour of submitting to the Council of the Society a proposal for constructing an apparatus which would have enabled any pressure to be measured by the successive additions of the pressure of a column of mercury of a fixed length; and working drawings of the apparatus were prepared by Mr. J. Cumine, whose services I am glad to have again this opportunity of acknowledging. An unexpected difficulty, however, arose in consequence of the packing of the screws (as I have already stated) not holding when the leather was in contact with mercury instead of water, and the apparatus was not constructed. For two years the problem appeared, if not theoretically, to be practically impossible of solution; but I am glad now to be able to announce to the Society that another method, simpler in principle and free from the objections to which I have referred, has lately suggested itself to me, by means of which it will, I fully expect, be possible to determine the rate of compressibility of hydrogen or other gas by direct reference to the weight of a liquid column, or rather of a number of liquid columns, up to pressures of 500 or even 1000 atmospheres. For the present it must be understood that, in stating the following results, the pressures in atmospheres are deduced from the apparent compressibility, in some cases of air, in others of hydrogen gas, contained in capillary glass tubes.

In this notice I will only refer to the results of experiments upon carbonic acid gas when alone or when mixed with nitrogen. It is with

indeed, that I have hitherto chiefly worked, as it is adapted for experiment; and the properties it exhibits will, in their main features, be found to represent those of other gases at corresponding temperatures below and above their

*of Carbonic Acid Gas.*—The following results have been obtained from a number of very careful experiments, and give, it is believed, the pressures, as measured by an air-manometer, at which carbonic acid gas liquefies for the temperatures stated:—

Temperatures in centigrade degrees.		Pressure in atmospheres.
0	.....	35·04
5·45	.....	40·44
11·45	.....	47·04
16·92	.....	53·77
22·22	.....	61·13
25·39	.....	65·78
28·30	.....	70·39

I am gratified to find that the two results (for 13°·09 and 13°·09) obtained in my former paper are in close agreement with these. On the other hand, the pressures I have found are in good agreement with those given by Regnault as the result of his elaborate investi-

liquefaction; but at the higher temperatures, which were considerably above the critical point of carbonic acid, there was no limit of this kind, and the pressures were carried as far as 223 atmospheres. I have only given a few of the results; but they will be sufficient to show the general effects of the pressure. In the following Tables  $p$  designates the pressure in atmospheres as given by the air-manometer,  $t'$  the temperature of the carbonic acid,  $e$  the ratio of the volume of the carbonic acid under one atmosphere and at the temperature  $t'$  to its volume under the pressure  $p'$  and at the same temperature, and  $\theta$  the volume to which one volume of carbonic acid gas measured at  $0^\circ$  and 760 millimetres is reduced at the pressure  $p$  and temperature  $t'$ .

*Andrews on the Physical Properties of* [June 17,

fully confirm the conclusions which I formerly deduced from the behaviour of carbonic acid at  $48^{\circ}$ , viz. that while the curve of the volume under different pressures approximates more closely to that of a perfect gas as the temperature is higher, the contraction is nevertheless greater than it would be if the law of Boyle held good for any temperature at which experiments have yet been made. From the foregoing experiments it appears that at  $63^{\circ} \cdot 7$ , carbonic acid gas, under a pressure of 223 atmospheres, is reduced to less than one half the volume it would occupy under one atmosphere, or to less than one half the volume it would occupy if it were a perfect gas and contracted in accordance with Boyle's law. Even at  $100^{\circ}$  the contraction under the same pressure amounts to  $\frac{1}{3\frac{1}{2}}$  part of the whole. From these observations I infer by analogy that the critical points of the greater number of gases not hitherto liquefied are probably far below the temperatures hitherto attained, and that they are not likely to be reached by liquids or solids, till much lower temperatures even than those reached by liquid nitrous oxide are reached.

*Lussac*.—That the law of Gay-Lussac in the case of the permanent gases, or in general terms of gases greatly above their critical points, holds good at least at ordinary pressures, within experimental error, is highly probable from the experiments made. The results I have obtained with carbonic acid will confirm the law of Boyle in the case of carbonic acid at ordinary pressures.

## Expansion of Heat of Carbonic Acid Gas under high pressures.

} . (C)

Taking as unit 1 vol. of carbonic acid at 6°·05 and 22·26 atmospheres, we obtain from series A the following values for the coefficient of heat for different ranges of temperature :—

$$\alpha = 0\cdot005499 \text{ from } 6^{\circ}\cdot05 \text{ to } 63^{\circ}\cdot79.$$

$$\alpha = 0\cdot005081 \text{ from } 63^{\circ}\cdot79 \text{ to } 100^{\circ}\cdot1.$$

From series B, with the corresponding unit volume at 6°·62 and 31·06 atmospheres, we find :—

$$\alpha = 0\cdot006826 \text{ from } 6^{\circ}\cdot62 \text{ to } 63^{\circ}\cdot83.$$

$$\alpha = 0\cdot005876 \text{ from } 63^{\circ}\cdot83 \text{ to } 100^{\circ}\cdot64.$$

And in like manner from series C with the unit volume at 6°·01 and 40·06 atmospheres :—

$$\alpha = 0\cdot009481 \text{ from } 6^{\circ}\cdot01 \text{ to } 63^{\circ}\cdot64.$$

$$\alpha = 0\cdot007194 \text{ from } 63^{\circ}\cdot64 \text{ to } 100^{\circ}\cdot60.$$

The coefficient of carbonic acid under one atmosphere referred to a unit volume at 6° is

$$\alpha = 0\cdot003629.$$

From these experiments it appears that the coefficient of expansion increases rapidly with the pressure. Between the temperatures of 6° and 64° it is once and a half as great under 22 atmospheres, and more than two and a half times as great under 40 atmospheres, as at the pressure of 1 atmosphere. Still more important is the change in the value of the coefficient at different parts of the thermometric scale, the pressure remaining the same. An inspection of the figures will also show that this change of value at different temperatures increases with the pressure.

interesting question, and one of great importance in reference to molecular action, is the relation between the elastic forces of different temperatures while the volume remains constant. The experiments which I have made in this part of the inquiry are only preliminary, and were performed not with pure carbonic acid, but with a mixture of about 11 volumes of carbonic acid and 1 volume of air. It is convenient, for the sake of comparison, to calculate, as is usually done, the coefficient of  $\alpha$  from these experiments; but it must be remembered that  $\alpha$  represents no longer a coefficient of volume, but a coefficient of pressure.

Table of a mixture of 11 vol.  $\text{CO}_2$  and 1 vol. air heated under a constant volume to different temperatures.

....	13.70	....	31.18
....	40.66	....	35.44
....	99.75	....	44.29

(A)

(B)

How far this relation will be found to exist under other conditions of temperature and pressure will appear when experiments now in progress are brought to a conclusion.

*Law of Dalton.*—This law, as originally enunciated by its author, is, that the particles of one gas possess no repulsive or attractive power with regard to the particles of another. “Oxygen gas,” he states, “azotic gas, hydrogenous gas, carbonic acid gas, aqueous vapour, and probably several other elastic fluids may exist in company under any pressure and at any temperature without any regard to their specific gravities, and without any pressure upon one another.” The experiments which I have made on mixtures of carbonic acid and nitrogen have occupied a larger portion of time than all I have yet referred to. They have been carried to the great pressure of 283·9 atmospheres, as measured in glass tubes by a hydrogen manometer, at which pressure a mixture of 3 volumes carbonic acid and 4 volumes nitrogen was reduced at 7°·6 to  $\frac{1}{3}\frac{1}{8}$  of its volume without liquefaction of the carbonic acid. As this note has already extended to an unusual length, I will not now attempt to give an analysis of these experiments, but shall briefly state their general results. The most important of these results is *the lowering of the critical point by admixture with a non-condensable gas*. Thus in the mixture mentioned above of carbonic acid and nitrogen, no liquid was formed at any pressure till the temperature was reduced below  $-20^{\circ}$  C. Even the addition of only  $\frac{1}{10}$  of its volume of air or nitrogen to carbonic acid gas will lower the critical point several degrees. Finally, these experiments leave no doubt that the law of Dalton entirely fails under high pressures, where one of the gases is at a temperature not greatly above its critical point. The anomalies observed in the tension of the vapour of water when alone and when mixed with air find their real explanation in the fact that the law of Dalton is only approximately true in the case of mixtures of air and aqueous vapour at the ordinary pressure and temperature of the atmosphere, and do not depend, as has been alleged, on any disturbing influence produced by a hygroscopic action of the sides of the containing vessel. The law of Dalton, in short, like the laws of Boyle and Gay-Lussac, only holds good in the case of gaseous bodies which are at feeble pressures and at temperatures greatly above their critical points. Under other conditions these laws are interfered with; and in certain conditions (such as some of those described in this note) the interfering causes become so powerful as practically to efface them.

the Power of the Eye and the Microscope to see Lines." By J. A. Broun, F.R.S. Received June 5.

Nobert's test-lines have been employed for the purpose of determining comparative powers of microscopes, several curious speculations have been made and conclusions arrived at by different well-known authorities as to the ultimate capability of that instrument and the ultimate atoms of matter. The lines in Nobert's test-plate were believed to approach to each other in a regularly diminishing series of distances, such that when the intervals left by the lines were about  $\frac{1}{80,000}$  of an English inch wide, no microscope higher than the theoretical power, could show the separation of

of the Great Exhibition of 1851, in the Report (p. 268), said that the lines in the first and second bands of a Nobert's test-plate could be distinguished with a power of 100 was sufficient, whereas to distinguish those in the third band a magnifying-power of 2000 was required. Dr. Carpenter (British Museum of Science and Art) considered this assertion and stated that if a power of 100 could show the lines when there were 1,000 to the inch (as in the first band), a power of 450 would show the lines when there were 50,000 to the inch (as in the

fied photographs of Nobert's test-bands by Dr. E. Carter, Surgeon of the U.S. Army. The results of this examination will be given at the end of this note.

I was induced meanwhile to examine the power of the eye, in order to compare it with the power of the microscope, and to determine what a microscope of given power should be able to show. The following observations had been made early in 1869, before I was acquainted with the observations of Dr. Jurin and of Tobias Mayer, to which I shall allude.

The first question which presented itself was as to the power of the eye to see single lines under the ordinary illumination of a northern sky.

*1st observation.*—A black line 0·042 inch wide, 1·75 inch long, drawn with common writing-ink on white paper, and a white line of the same width and length between two black lines, each 0·20 inch wide, were seen equally well within a room lighted by a window to N.W. at a distance of 30 feet, the angle subtended by the width of the lines being 24" nearly.

*2nd observation.*—A dark-brown hair, 0·0026 inch wide, 2·5 inches long, was fixed by dots of transparent gum-arabic to the window-pane, and was seen against the N.W. sky by a young eye at 36 feet (I could not see it myself at a greater distance than 30 feet): the diameter of the hair subtended an angle of 1"·24 at the eye. The same eye examined fine lines divided on glass at a distance of 6 inches, and, other things equal, should have been able to see a line  $\frac{1}{27,700}$  inch wide at that distance. [June 5, 1875. I find that a young eye can see lines on glass  $\frac{1}{10,000}$  inch wide,  $\frac{1}{25}$  inch long, angle 3"·5 nearly.]

Dr. Jurin could see a silver wire  $\frac{1}{468}$  inch diameter placed on white paper when the diameter subtended an angle of 3"·5, and a silk fibre one fourth the diameter of the wire when it subtended an angle of 3"·35\*.

*3rd observation.*—Whether the length of the line affects its visibility. The hair just observed was cut into pieces of different lengths and fixed, as before, to the window-pane; they could be seen at the following distances :—

Length of hair.	Distance seen.	Angle subtended by	
		Diameter.	Length.
in. 0·90*	feet. 37	1"·21	413"
0·25	32	1·39	134
0·133	22	2·03	104
0·020	10	4·46	86

\* See Jurin's essay on distinct and indistinct vision in Smith's 'Complete System of Opticks,' 1738. I am acquainted with Jurin's observations from the Rev. Father Pezenas's translation of Smith's work, 'Cours complet d'Optique,' 1767, p. 282.

0 inch long was one foot further off than that 2.5 inch long preceding (2nd observation). The difference was due, partly to a different light of the sky.

con.—The previous observation shows that the line is seen at a distance as the length increases till a limiting angle is attained, which increase of length has no effect on the visibility. The observations were made to determine approximately the law of visibility to length.

Different lengths, 0.045 inch wide, were drawn on different paper (5.8 by 4.5 inches); the papers were pinned successively and placed vertically in the shade (out of doors) with a clear sky (P.M.); the mean distance of disappearance on retiring and on approaching the lines was taken.

Length.	Distance	Angle subtended by			$= \sqrt[3]{\beta}$ .
		Length $\beta$ .	Width $\alpha$ .		
			Observed.	Calculated.	
	feet.	"	"	"	
0.45	"	41	14.6	14.5	50
0.55	53	62	11.4	11.2	45
0.70	68	96	9.2	9.2	42

*5th observation.*—Four dark-brown hairs having been arranged on paper at equal intervals by means of modeller's wax attached to the ends, and then fixed at the ends with gum-arabic, the paper was cut away between the ends, and the two slips of paper to which the ends were gummed were fixed to the window-pane: the diameter of the hairs was  $\frac{1}{3125}$  inch (0·00267) very nearly, the lengths were nearly 1 inch, and the intervals were very nearly the same as the diameter of the hair, the whole width being 0·019 inch. The hairs could be seen to be more than one at 28 inches distance, and they could be counted at 21 inches; the angles subtended by the intervals at these distances were 20" and 26"·5 respectively.

It thus appears that at a distance greater than 28 inches the four hairs appeared as one, when each hair subtended an angle sixteen times greater than it could be observed at when seen alone (see the 3rd observation). This curious fact was pointed out by Dr. Jurin in the essay already cited. He found when two pins were placed near to each other on a window, that the interval between them could not be perceived when it subtended an angle of 40", whereas a single pin could be seen at an angle of from 2 to 3 seconds. Mayer, who also made observations on parallel lines nearly twenty years after Jurin, does not seem to have remarked this fact\*.

The 5th observation was repeated with four white hairs from a horse's tail; these were arranged at equal intervals, the mean diameter of the hair being 0·0105 and the mean interval 0·0110 inch. The hairs could be seen to be more than one 9 feet distant, when the angle subtended by each hair was 23"·1; and the hairs could be counted at 6 feet distant, when the angle was 30"·7. These angles are about one sixth greater than for the human hairs, the difference being probably due to the difference of light, and perhaps partly to the different length, which was not noted†.

*6th observation.*—A series of lines 0·7 inch long were drawn on separate slips of paper with different widths and intervals. The papers were fixed successively to the wall of a room lighted by a window to N.W., the light falling at an angle of about 45° on the paper. The following Table contains the results of the observations, first, when the intervals and lines were of equal width, and, second, when the intervals were 1, 2, 3, ... times the width of the lines.

\* Mayer's observations are given in Pezenas's translation of Smith's 'Optics,' t. ii. p. 409. I am not acquainted with the original memoir. As already stated, Jurin's and Mayer's observations were known to me only after the above observations had been made.

† Dr. Jurin has given, as an example of the difficulty of counting parallel lines, the following series:—

and has shown the advantage of employing commas in such numbers as the following, 100000000000 and 100,000,000,000.

Lines and intervals equal.		Lines and intervals unequal.			
Distance.	Angle.	Width of		Distance.	Angle.
		Lines.	Intervals.		
feet.		in.	in.	feet.	
8.3	44	0.041	0.021	9.5	37.0
15.5	45	0.045	0.079	21.7	38.0
25.0	50	0.043	0.121	28.5	28.0
36.7	55	0.044	0.164	34.0	22.0
47.5	59	0.044	0.203	39.0	19.4
		0.045	0.241	40.5	19.0
		0.044	0.477	55.5	13.5

Lines and intervals were equal, the angle increased from the smallest (0.021 inch) to the largest (0.164 inch); the greater angle for the greatest width (0.081) is probably connected with some irregularity in the increase of the angle at the greater distance is probably due to the constancy of the length of the lines (see 8th observation).

When lines and intervals are unequal, the angle subtended by the line diminishes as the interval increases; the limiting angle is that at which a single line 0.70 inch long and 0.044 inch wide is seen.

It was now sought to determine in what degree the

lines. On the other hand, the tint may be made so faint as to be imperceptible at 6 inches (the distance for a young eye of faint or small objects). The preceding observations are represented nearly by the following formula :—

α-56 = 19.2 / (1.55^t - 1) .....(2)

where α is the smallest angle (in seconds) at which the separation of the lines was visible, and t is the tint or number of the coats of watered ink. The calculated values are given in the Table.

When t=1/8 (of the first tint) the lines, according to the formula, should have been just visible at 8 inches from the eye, or a weaker shade on white paper than that made by one drop of the first tint with forty-six drops of water could not have been seen. On the other hand, when t=12, the difference of the angle of visibility from that for absolute blackness is only 0".1. The constants in this and the other formulæ will depend of course on various circumstances of illumination, the state of the individual eye, &c.

Mayer made a series of observations with several parallel lines drawn with China ink on white paper (well stretched), the width of the lines and intervals in one case being 0.032 of an English inch (0.36 de ligne). These lines he could perceive to be several at 11 feet (pieds de Roi) distance with the light from an open window to north, or when the angle subtended by the interval was 47". He then made observations with the same lines lighted by a wax candle placed at different distances from them.

I give Mayer's observations for this set of lines here for comparison with the preceding results for different tints.

D.	d.	a. Observed.	Angle α, calculated by					
			(3).	Error.	(5).	Error.	(6).	Error.
feet.	feet.	"	"	"	"	"	"	"
7.47	0.5	69	63	- 6	66	- 3	69	0
6.53	1.0	79	79	0	78	0	79	0
5.73	2.0	90	99	+ 9	96	+ 6	92	+ 2
4.73	3.0	109	114	+ 5	108	- 1	103	- 6
4.48	4.0	115	125	+ 10	118	+ 3	112	- 3
3.51	8.0	147	158	+ 11	146	- 1	141	- 6
3.00	13.0	172	185	+ 15	172	0	172	0

Mayer considered that he explained his result by supposing the limiting angle (α) of distinct vision to be as the cube root of the distance of the candle from the paper, or

α=79 √[3]{d}, .....(3)

where α is in seconds and d is in *pieds de Roi*. He also arrived at the following curious conclusion. Since the limiting value of α for the

full daylight was 47", by substituting this value in equation  $d=0.2$  foot; and "we may conclude," he says, "that the as strong as that of a candle at one fifth of a foot from the frequently if we wish to light an object with a candle as would be by daylight [and even by strong sunlight, as we must employ twenty-five lighted candles placed at a foot from the object"]!

's formula been an exact representation of the observations, concluded that the eye could separate parallel lines as well as five candles at one foot distance as with full sunlight; but it that the errors of the formula increase as  $d$  increases and An equation of the form given by Mayer which best represents observations is found by least squares to be

$$\alpha = 77.6 d^{\frac{1}{2.57}}; \dots \dots \dots (4)$$

fails when  $d$  is small. The following equation best represents observations, including that for daylight:—

$$\alpha - 47 = 25 \sqrt{d} + 30 \log (d + 0.9). \dots \dots \dots (5)$$

0,  $\alpha = 48''.3$ . The errors of this equation are given in the e. But it will be seen here also, from the distances  $D$  of which I have calculated from the angles given by Mayer, distance  $d$  of the candle increase in a geometrical pro-

the lines receives no improvement in the first case by any increase of depth of tint of the lines beyond a certain feeble shade, nor in the second (Mayer's) case by any increase of the illumination of both lines and spaces beyond that of a candle held near.

8th observation.—It was sought whether the visibility of parallel lines increased with their length, as in the case of single lines. Four long parallel lines having been drawn, of the width and at the interval of 0·048 inch, on a sheet of white paper, this was pinned, as before, to a smooth plank and placed in the open air in the shade (before sunset); the lines were covered by a sheet of the same paper so as to show variable lengths. The following Table contains the results of the observations :—

<i>l.</i>	D.	<i>a.</i>	(7).	Errors.	<i>β.</i>
in.	ft. in.				
0·4	16 8	49·5	49·5	0·0	413
0·8	17 4	47·6	47·4	−0·2	794
1·6	18 5	44·8	45·5	+0·7	1490
3·2	18 10	43·8	43·8	0·0	2921
6·4	19 5	42·5	42·1	−0·4	5664

D is the distance of the observer, *l* the length of the lines, *β* is the angle subtended by the length at the eye of the observer; *a*, the angle subtended by the width of the lines, is represented nearly by the following formula :—

$$a = \frac{352}{\log l + 4\cdot53}, \dots\dots\dots (7)$$

where *l*, the length of the lines, is expressed in units of 0·001 inch. The variation of the angle is comparatively small in this case. The law of variation of *a* seems to change when the length of the lines becomes less than the width of the whole.

9th observation.—The following observations were made with short parallel lines drawn *separately* on the same sheet, with the same width of intervals and lines as in the last case :—

<i>l.</i>	D.	<i>a.</i>	(8).	Errors.	<i>β.</i>	$\frac{a^2}{\beta}$

The observations are represented nearly by the equation

$$a = \frac{137}{\log l + 0\cdot27}, \dots\dots\dots (8)$$

It will be seen that the angle *a* increases rapidly as the length dimi-

282

the other hand,  $\beta$ , the angle subtended by the length of the lines, decreases much more rapidly. In this case, as in that of the 4th case, we find  $\alpha$  and  $\beta$  are connected nearly by the following

$$\alpha \sqrt{\beta} = \text{constant} \dots \dots \dots (9)$$

Observation.—The long parallel lines were seen by different persons at different distances when inclined to the horizontal by an angle of 45°. When viewed from the right and above it to the left, but the visibility was different at different angles for different persons.

Observation.—Jurin's observations of the difference of visibility of a single line and a single line had reference to the case of only two black lines with a white line between. On comparing the distances at which a single line could be seen 0.4 inch long and of the same width and height as before (0.048 inch), it was found that it was most difficult to see a single line when there were only two. The following are the observations:—

Number of lines.	D.		$\alpha$ .
	ft.	in.	
1.....	50	0	16
2.....	13	4	62
3.....	15	0	55
4.....	17	2	48

from bands near the middle of the photographs, there could be no doubt whether the line was a fringe or not.

The following Table contains the results of these observations:—

Measures of Nobert's Test-lines.

Band.	Number of lines.	Width of		Number to the inch.			Ratio.

*Notes.*—These measures are frequently mere approximations; and in several bands the graving-point has made a wonderful approach to an equality of width of lines and spaces; indeed these lines are marvels of mechanical skill. If, in the case of each band, the first and last lines had been drawn longer than the rest, it would have been possible to measure the width of a line with considerable accuracy, since, as has been shown, the visibility of a single line is nearly twenty times that for the series.

The widths of the lines and spaces are those taken from the photographs, the unit being  $\frac{1}{1000}$  inch. The photographs are magnified to 1000 times. In bands XVII. and XVIII. second measures are given from photographs magnifying to 1600 times (but reduced to the same unit). The number of lines in ( ) are the numbers counted for which the total width was measured. The number for the XIX.th is deduced from the measure of a few where the lines were most distinct. The numbers of lines and spaces to an inch are the numbers which could be put in an inch laid side by side (without interval). Under "Both" is given the number of lines to the inch (with interspaces), as in the bands. The "Ratio" is that of the number for the widest space (17,000 to the inch) to the number for the widest line or space in the following bands.

It will be seen that the least width of the lines which can be counted and measured on the photographs is about  $\frac{1}{160,000}$  of an inch (XIII.th band). We have seen (5th observation) that dark parallel lines on glass can be seen with transmitted light when their width subtends an angle of 20" to 26"; so that lines stopping the light moderately (7th observation) of  $\frac{1}{160,000}$

XI. "On the Change produced by Magnetization in the Electrical Resistance of Iron and Steel.—Preliminary Notice." By Professor W. G. ADAMS, F.R.S. Received June 1, 1875.

For some time past Mr. Herbert Tomlinson, Demonstrator in the Physical Laboratory of King's College, has been engaged in carrying out a series of experiments on this subject, and also on the effect of change of tension on the electrical resistance of steel and iron wires.

In measuring the resistances of the short lengths of the wires or rods which were employed, a unit was chosen which was a small fraction of the British-Association unit.

Experiments were made with rods of soft iron about one eighth of an inch thick, with soft steel, and also with steel of different degrees of hardness.

With a rod of soft iron about 3 feet long there was an increase of resistance of about 1 per cent. on magnetizing with two Grove's cells. The whole resistance of this rod was 32 units.

The experiments were repeated with the rod placed in ice and also in water at the ordinary temperature (about  $15^{\circ}$  C.), and with nearly the same change in the resistance of the rod. The change in the temperature of the water was found to be about  $1^{\circ}$  C. during the experiment.

Another rod of soft iron was employed whose resistance was 50 units. The magnetizing current was measured by means of a tangent-galvanometer, and the resistance was measured by means of Wheatstone's bridge. There was found to be an increase in the resistance of the rod when it was converted into a magnet by sending the magnetizing current through a wire which was coiled round it in the form of a spiral.

It was found that the electrical resistance was increased when any addition was made to the strength of the magnetizing current. When the increase in the electrical resistance was divided by the square of the strength of the magnetizing current, a series of numbers was obtained which did not differ much from one another; the values of these numbers mostly lie between 3 and 4.

When the magnetizing current is considerably increased, the ratio of the increase in the resistance to the square of the magnetizing current diminishes rather rapidly.

A similar series of experiments was made with a thick knitting-needle made of *soft steel*. The resistance of the needle was 29 units. In this case also the resistance was found to *increase* when the strength of the magnetizing current was increased. On dividing the increase of resistance by the square of the magnetizing current, the numbers obtained from a considerable number of experiments lie between 4.7 and 5.6, showing that the ratio of the increase of resistance to the square of the magnetizing current is very nearly constant.

*The Electrical Resistance of Iron and Steel.* [June 17,

magnetizing current is considerably increased, this ratio is

nds of *hard* steel were tried.

inary knitting-needle, of which the resistance was 66·5

izing with currents of different strengths, there was found  
tion in the resistance; and it was also found that the diminu-  
nce increased when the strength of the current was increased.  
s varying from  $\tan 15^\circ$  to  $\tan 54^\circ 30'$  the diminution  
1·33, i. e. about 6·5 per cent. of the whole resistance. The  
increased about  $2^\circ$  C. during the experiment.

he loss of resistance by the square of the magnetizing  
results of four sets of experiments gave the following

$$\frac{.165}{(\tan 15^\circ)^2} = 2.29,$$

$$\frac{.7525}{(\tan 30^\circ)^2} = 2.26,$$

$$\frac{2.3225}{(\tan 45^\circ 30')^2} = 2.24,$$

$$\frac{4.330}{(\tan 54^\circ 30')^2} = 2.21.$$

current there was found to be also a diminution of resistance in the case of hard steel, and an increase of resistance in the case of soft iron and soft steel.

Thus the effects produced are the same as those due to transverse magnetization by a neighbouring current.

Conclusions to be drawn from the experiments:—

(1) The effect of passing any current through a bar of hard steel is to diminish its resistance, and through a bar of soft iron or soft steel is to increase its resistance.

(2) When a bar of hard steel is magnetized by sending a current through a coil which encloses it, there is a diminution of resistance which is directly proportional to the square of the magnetizing current up to a certain limit.

(3) When soft steel or soft iron is magnetized longitudinally or transversely, there is an increase of resistance which is nearly proportional to the square of the magnetizing current.

## XII. "The Action of Light on Selenium." By Prof. W. G. ADAMS, M.A., F.R.S. Received June 17, 1875.

(Abstract.)

The paper contains an account of several series of experiments made in December and January last on this subject with the view:—

(1) To determine whether the change in the electrical resistance of the selenium is due to radiant heat, light, or chemical action.

(2) To measure the amount of the change of resistance due to exposure to light from different sources and through various absorbing media.

(3) To determine whether the action is instantaneous or gradual, and, if possible, to measure the rate at which the action takes place.

The selenium formed one of the four resistances in a Wheatstone's bridge, and its average resistance was about  $2\frac{1}{2}$  megohms.

The two resistances in the bridge, which were kept constant, were 4 and 2000, so that the resistance of the selenium was 500 times the variable resistance required to balance it.

R is taken to represent this resistance required to balance the selenium. The box containing the selenium was laid on its side and had a draw-lid, which was kept closed except when exposure was made. In front of the draw-lid was a black screen with an opening opposite to the selenium 6 centims. by  $3\frac{1}{2}$  centims., into or in front of which various absorbing media could be placed.

The absorbing media employed were bichromate of potash, sulphate of copper, ruby, orange, green, and blue glasses. Plates of rock-salt, alum, mica, and quartz were also employed.

With the lid of the box on, the resistance of the selenium was measured, and was found to increase slowly and regularly in consequence of the

current. In most of the experiments a battery of 30 Le-  
was employed.

and that the higher the battery-power the less is the resistance  
m. Experiments with 5, 30, and 35 cells gave the follow-

Resistance R with	5 cells	.....	5400 ohms.

tion of resistance with increased battery-power may be  
in part by leakage from the rheocord ; and there may be  
ing electromotive force similar to polarization brought into  
elenium when the current is passing which increases with

light diminishes the resistance of selenium.

accounted for by either of two hypotheses :—

light acting on the selenium sets up a polarization current  
which opposes the battery current passing through it.

action through media which absorb all the more chemically active rays is very nearly as great as when they are not interposed, so that the chemical rays produce very little effect.

Experiments with the lime light, with rock-salt, alum, and quartz, and their combinations, two together, show that the resistance diminishes at the same rate as the illumination increases. This seems to show that the action is almost entirely due to the illuminating power of the light falling on the selenium.

Experiments with the electric light, with smoked rock-salt, alum, and a solution of iodine in bisulphide of carbon show that the obscure heat-rays do not act powerfully on the selenium.

In one series of experiments an attempt was made to separate the instantaneous effect from the gradual effect of the light.

This was done by first balancing the resistance of the selenium before exposure by a resistance  $R$  of the coils, then diminishing  $R$  by 300, 400, or 500 ohms, according to the brightness of the light, so as to get no sudden deflection when the current is made at the first instant of exposure.

It was difficult to determine beforehand by estimation what diminution of  $R$  should be made; but after several trials it was quite possible to make the sudden deflection very small, either on one side of the zero or the other, and to keep the needle near the zero by continuing to diminish the value of  $R$  as long as the exposure lasted.

In this way the effects of exposure in successive equal intervals of time can be measured.

The light allowed to pass through the coloured glasses and other absorbing media was examined by a spectroscope, and it was found that the yellowish-green rays were among the most active in altering the electrical state of the selenium.

A series of experiments was made to determine the effect of light from different sources.

A Bunsen burner was employed, and chloride of barium, chloride of strontium, thallium, and sal-ammoniac were introduced into the flame.

The effect with barium seemed to be less than with strontium.

With sal-ammoniac in the flame the effect was as great as with strontium and more lasting.

With thallium the effect was considerably greater, more gradual, as well as far more lasting than with strontium.

The effect on repeating an experiment is very much less than the effect of the first exposure with each new source of light.

Experiments were made with the Bunsen burner alone in its ordinary state and when it is rendered luminous by stopping the air-holes.

Exposure to the ordinary Bunsen flame for several seconds only caused a slight deflection of about 10 divisions of the scale. After this slight diminution of resistance the needle gradually returned to zero, and was

*On the Action of Light on Selenium.*

[June 17,

the other side, as the heat radiated from the Bunsen burner by the selenium.

the flame luminous, the needle was suddenly deflected off great rapidity.

shunt to the galvanometer there was no deflection on extraordinary Bunsen flame ; but with the luminous flame there deflection, which increased to 250 divisions of the scale in a

responded to a change of resistance in  $R$  of about 1250 ohms.

ment was repeated in a slightly different way. The sele-

anced, and before exposure to the *luminous* Bunsen flame,

shed by 1000 ohms. On making contact and exposing at

ant, there was a slight deflection, showing that the sudden

ivalent to rather less than 1000 ohms ; but in a very few

needle was at rest at zero, and to keep the needle at zero

was further diminished by 300 ohms.

ce had been diminished by one fourth of its whole amount

he minute in consequence of the exposure.

an ordinary wax taper diminished the resistance of the

00,000 ohms, or about one eighth part of its whole resist-

ing powers of these sources of light were compared by

ment was made at the half-moon, when the moon was high up, so that the light fell obliquely on the window and did not shine directly on the selenium.

On throwing the moonlight on the selenium by means of a plane mirror, the needle was at once deflected 20 divisions of the scale; on placing the mirror outside the window so as to send the moonlight perpendicularly through the window on the selenium, the deflection of the needle was 40 divisions. The window was kept closed during these experiments.

On another evening when the moon shone very obliquely on the window, and the selenium was exposed on the inside of the window directly to the moonlight, the needle was deflected 100 divisions of the scale, and the deflection increased to 150 divisions after exposure for about 3 minutes.

The change in the resistance of the selenium was from 60,000 to 70,000 ohms.

These experiments show that the action on the selenium is due principally, if not entirely, to radiations belonging to the visible part of the spectrum. Light rays of all kinds, particularly the greenish yellow, produce an instantaneous effect followed by a more or less gradual effect, which continues to increase during exposure for several minutes.

These facts suggest two hypotheses as possible explanations, which may help as guides in further experiments, but which cannot be accepted as proved without further evidence.

(1) That the light falling on the selenium causes an electromotive force in it, which opposes a battery-current passing through it, the effect being similar to the effect due to polarization in an electrolyte.

(2) That the light falling on the selenium causes a change on its surface akin to the change which it produces on the surface of a phosphorescent body, and that in consequence of this change the electric current is enabled to pass more readily over the surface of the selenium.

### XIII. "On the Production of Glycosuria by the Effect of oxygenated Blood upon the Liver." By F. W. PAVY, M.D., F.R.S. Received June 17, 1875.

In a communication on "Lesions of the Nervous System producing Diabetes," presented to the Royal Society in 1859 (Proc. Roy. Soc. vol. x. 1859-60), I made known that division of certain parts of the sympathetic system occasioned the presence of sugar in the urine. The effect of puncturing the floor of the fourth ventricle (Bernard's celebrated experiment) had been for some time previously familiar to physiologists; but nothing had been ascertained about the production of diabetes by lesions of the sympathetic, until my experiments upon the subject were conducted; and it was in attempting to discover the channel through

W. Pavy on the Production of Glycosuria. [June 17,

*Ascaris oblongata* influenced the liver, that I was led to recognize which my researches disclosed.

It merely showed that there were other means besides the floor of the fourth ventricle by which artificial diabetes could be produced. They did not explain the reason of the appearance of the sugar. I all sought to discover something upon this point. Failing to find any explanation that has been suggested with the evidence of experiment, I have from time to time pushed inquiry in various directions, but always with a fruitless issue, until the summer of 1866 came across the results which it is the object of this communication to make known, a brief announcement of them having been made in a letter to the Secretaries of the Royal Society shortly after the close of the session of last year.

In the past I have been led to look to an altered condition of the liver as likely to prove the most probable cause of the transformation of amyloid substance into sugar, which evidently is the foundation of the artificial diabetes following operations upon the nervous system. Schiff is of this view, and ('*Journal de l'Anatomie et de la Physiologie*,' Paris, 1866) has referred the escape of sugar from the blood and thence the production of glycosuria, to the development of amyloid in the blood as a result of the hyperæmia which follows operations on the nervous system which occasion artificial diabetes. It is necessary, according to his view, that there should

contained in the blood should fail to be capable of determining the production of sugar whilst passing through the vessels of the liver.

Having so far proceeded without success, it now occurred to me to try the effect of introducing defibrinated arterial blood into the portal system. I was led to experiment in this way from having a long time previously observed that when arterial blood only was allowed to flow through the liver (as, for instance, when the portal vein was tied and the hepatic artery left free), sugar escaped from the organ to such an extent as to render the contents of the circulatory system strongly saccharine. This result I had commented upon as being somewhat surprising, and as furnishing evidence standing in opposition to Bernard's glycogenic theory. I had not succeeded by the operation in producing glycosuria, because, as it appeared to me, no urine was secreted, owing to the ligation of the portal vein leading to such a diversion of blood from the general circulation, by the accumulation occurring in the portal system, that the flow through the kidney was too slight to allow of it. I had endeavoured to overcome this obstacle by connecting, through the medium of a canula, the portal with the right renal vein after ligaturing the corresponding renal artery. If the experiment had succeeded, the liver would have been left with its arterial supply, but the portal stream would have been diverted and made to reach the inferior cava without traversing the hepatic vessels. As regards the operation, this I found I could accomplish; but each time I performed the experiment the object I had in view was frustrated by the canula becoming quickly filled with a plug of blood-clot. It was whilst under this difficulty that I thought of collecting blood from an artery, defibrinating it, and then introducing it into the portal system. I had considered it possible that some slight effect might be perceptible, but had not anticipated the strongly marked result which is producible.

The amount of blood used has been from 10 to 18 fluid ounces. After the production of anæsthesia by chloroform the blood was collected from the carotid artery, stirred in order to defibrinate it, strained, and then very slowly injected into a branch of the mesenteric vein. In one experiment, where half an hour had been employed in making the injection, the urine, at the completion of the operation, contained a notable amount of sugar, and half an hour later showed, by analysis, the presence of 15 grains to the fluid ounce. In a second the urine contained 10 and in a third 14 grains to the fluid ounce when collected three quarters of an hour after the operation.

The experiments were performed upon dogs, and in each case it had been ascertained that the urine was devoid of sugar before the operation.

It will thus be seen that these results leave no doubt about the decided production of glycosuria. The effect was not only rapid but of a strongly marked character. It is necessary, however, before concluding that the glycosuria was really attributable to the influence of the oxygenated blood, to have evidence that in the absence of oxygenated blood

W. Pavy on the Production of Glycosuria. [June 17,

would be obtained. I took care, by slowness of injection, making the circulation through the liver to be influenced by increased pressure within the portal system. I am not, I do not think from my previous experience, that any fallacy is likely to arise from such a source; but I nevertheless deemed it expedient to exclude the possibility of its occurrence.

Since the effect which has been described from the injection of oxygenated blood into the portal system, it became necessary to determine positively that it was attributable to the oxygenated condition of the blood and not to any other cause. To decide this point an appropriate counterpart experiment was made. Defibrinated venous blood was injected into a branch of the mesenteric artery on each occasion where such an operation has been performed. The same result has been obtained. With the evidence thus far obtained, the conclusion may be warrantably drawn, that oxygenated blood in this manner influences the liver, so as to lead to the production of sugar.

It may be inferred that, contrary to the effect of venous blood in its natural state of the circulation, it promotes the transformation of starch substance into sugar.

In the course of these experiments of injecting defibrinated blood into the portal system, I came across an effect which I had not anticipated, and which on several occasions frustrated the object I had in view. It is well known, as experimental physiologists know, may be injected

XIV. "On some supposed changes Basaltic Veins have suffered during their passage through and contact with Stratified Rocks, and on the manner in which these Rocks have been affected by the heated Basalt." By I. LOWTHIAN BELL, F.R.S. Received May 27, 1875.

The northern counties of England afford very satisfactory evidence of the intrusion, in former geological times, of a large area of fused matter beneath portions of the then-existing surface, and through the vertical, or nearly vertical, faults and fissures of thin sedimentary strata.

Through the observations and writings of N. J. Winch\*, Sir Walter Trevelyan†, Prof. Sedgwick‡, William Hutton§, John Buddle||, Nicholas Wood¶, Westgarth Forster\*\*, and several other observers of earlier†† and more recent‡‡ date, we have been made acquainted with many details of the existence, appearance, and direction at the surface of extensive whin-dykes and beds of intercalated trap, basalt, or whin, using the terms which have hitherto been generally and locally applied to the igneous rocks found in connexion with the Carboniferous formation of these districts.

In the most northerly part of Northumberland a broad dyke of igneous rock occurs on Holy Island, and is continued on the mainland to the west. Several other dykes, too numerous, indeed, to be specially mentioned in this communication, occur in the Carboniferous rocks between this locality and the banks of the Tees, having for the most part a direction from west to east. In addition to the dykes which may have filled up old lines of faults and fissures, we have bedded igneous rocks, where fused matter, instead of coming to the surface, has forced its passage or way, horizontally between the regular and previously stratified sedimentary rocks. Sometimes also the igneous matter is found between the central portions of individual beds of shale and limestone, and in its course has oftentimes enclosed in its mass considerable portions of such preexisting beds, as in the examples figured by Prof. Sedgwick in the second volume of the Cambridge Philosophical Transactions.

sill, as it is termed by the lead-miners of the Alston-Moor, the most remarkable example of bedded igneous rock in the county, extending as it does from the Farne Islands in the county of Northumberland; and after passing the Stublick, which it is faulted, it skirts the escarpment of the Pennine Waterop, and terminates, so far as we are informed, in the valley of Lunedale in Yorkshire.

Another but smaller occurrence of bedded basaltic rock near Weardale, which was formerly, and very accurately, described by Trevelyan in the first volume of the 'Transactions of the Geological Society of Northumberland and Durham.'

A lateral intrusive mass of whin exposed by denudation at the village of Bolam, in South Durham, in connexion with the celebrated Fell Dyke. This mass has been figured and graphically described by Prof. Sedgwick in the Cambridge Transactions above mentioned.

An instance of the lateral or horizontal intrusion of igneous rock which we have now to describe occurs in connexion with the basaltic dyke which extends from Egglestone Moor along the Bedburn Beck, near Burn Colliery, Coustantine Farm, Whitworth, Tudhoe, Hett, and Crow Trees, to Quarrington Hill, on the escarpment of the Pennine. This dyke was first described, and its direction

In the mean time a neighbouring firm had sunk a pit in the immediate vicinity without meeting with any trace of whin rock; and as circumstances demanded it, two shafts were commenced by Messrs. Bell Brothers 185 yards N.E. of the first bore-hole. The area within these three points amounts to something like 15 acres. When the more advanced of these pits was sunk to a depth of 67 fathoms, the men came upon the hard obstacle met with in the bore-holes; and the same thing happened in the second shaft, situate 60 yards to the west of its neighbour.

In each case fully four months of incessant labour, accompanied with considerable expense, was required before the lower surface of this hard stratum was reached, which proved to have a thickness of 19·75 feet. In all probability, however, its dimensions are subject to considerable fluctuations, for in one of these two pits the bed is 4 feet thinner on the north side of the shaft than on the south.

It was now clear that it was a bed of basalt lying in a horizontal position which was encountered, in which direction it had spread itself as one offering less resistance than that to be overcome by forcing an exit at the surface. At what point a communication exists between this interjected mass and its subterranean source we have had no means of ascertaining.

Above and below the basaltic bed, as found in the pits, there are two well-known seams of coal. In the neighbouring colliery spoken of (Littleburn) these are separated by 50·25 feet of fire-clays, shales, and sandstones, while in the present case the intervening rocks measure 103·66 feet, showing an increase of 53·41 feet. Of this only 19·75 feet is due to the whin, the remaining 33·66 feet arising from a thickening of the sandstone and other deposits.

During the entire progress of sinking specimens of the rocks were preserved, which enabled me at my leisure to examine not only the whin but also the altered character of the adjacent strata.

The change experienced by the latter has frequently formed the subject of comment; but I am not aware that much attention has been directed to any modification in the composition of the basalt itself, caused by contact with the substances through which it had penetrated.

It would of course be highly instructive if any sedimentary rock could be accepted, in respect to its constituents and their relations to each other, as a normal type of whinstone. If, for example, an aqueous rock were found in the immediate vicinity of basalt, and the compositions of both were the same, one might infer the physical difference to be due to the mere influence of igneous action.

There are, however, to be found in nature many substances which more or less resemble in constitution the matter filling whin-dykes, clay-slate being one, some specimens of which contain the following ingredients:—

Silica .....	54
Alumina .....	24
Protoxide of iron .....	14
Magnesia .....	5
Potash .....	3
	<hr/>
	100

ould be nothing extravagant in the supposition that clay-character reduced to a state of fusion by heat might be red in passing through the Mountain Limestone and Mill- ere reaching the surface in the county of Durham, and that resemble the composition of the whin-dykes of the district. Dyke and its parallel one derive their origin from one e, and if changed by subsequent contact with other rocks red in each case by the same cause, is apparent on refer- espective compositions.

	Hett Dyke.	Parallel Dyke.
.....	51.35	50.60
Alumina.....	17.61	17.38
oxide of iron .....	12.04	12.22
.....	9.65	9.20
Magnesia ... ..	5.68	5.66
.....	1.00	1.00

something under this in the other case. These coatings exhibit a marked similarity to each other; but a striking difference in some respects is observed to the interior of the mass they surround.

	Upper surface.	Lower surface.
Silica .....	43.22	40.62
Alumina .....	17.44	18.18
Protoxide of iron .....	13.03	14.00
Sulphide of iron .....	....	1.31
Lime .....	6.26	4.37
Magnesia .....	2.86	3.94
Potash .....	} 1.28	.78
Soda .....		.33
Carbonic acid .....	14.72	13.23
Water .....	1.46	2.36
	<hr/> 100.27	<hr/> 99.12

In colour these coatings are of a light buff, and are close in texture, in both of which particulars they differ considerably from the unchanged basalt. It would appear that any difference in composition between the interior of this horizontal bed of basalt and its outer surfaces is entirely independent of that which might be supposed to arise from mere contact with the adjoining strata. Lying above it is 8 feet of a siliceous rock known among miners in the North of England as a "white post." It was found to consist of:—

Silica .....	88.25
Alumina .....	5.69
Peroxide of iron .....	1.71
Lime .....	1.53
Magnesia .....	.69
Potash .....	.80
Soda .....	.21
Water .....	1.75
	<hr/> 100.63

The underside of the basalt rests upon a thin seam of coal, greatly charred by its proximity to so large a volume of matter, which must have arrived at its present position in a state of intense heat. This coal is of course deficient in volatile constituents, and contains a large percentage of ash, one half of which is carbonate of lime. Its composition is as follows:—

Carbon .....	56.58
Hydrogen .....	1.00
Oxygen .....	3.52
Sulphur .....	.18
Ash .....	38.65
	<hr/> 99.93

erved that, in the first three instances quoted of the composition of whinstone, carbonic acid is named as a constituent varying from 1.02 to 2.57 per cent. of the whole. This is a little remarkable confirmed by actual experiment that when protoxide of iron, potash, and soda, in the form of carbonates, are fused with silica in the proportions in which these substances are found in the whin, the resulting mass does not contain, as might be expected, a trace of carbonic acid. Whether the small quantities of this acid represent portions which under immense pressure do not escape from the lime with which it was perhaps combined, is a question to which no satisfactory answer can be

On the other hand, it is not improbable that basalt may, after or during the act of cooling, be placed in circumstances where it may be absorbed by such of its constituents as are known to combine with it.

Some experiments were tried on a sample of the pounded whinstone previously ascertained to contain 1.97 per cent. of carbonic

per cent.  $\text{CO}_2$

Some of the samples having been exposed during four days to dry

position of the outer coverings of the basalt, already described. These in all probability would, from their position, be more freely exposed to the action of carbonic acid than the interior of the mass of which they formed the coating. That these portions are in reality identical with the bed itself, merely altered by the rate of cooling, or by a change in composition due to absorbing carbonic acid, or by these causes combined, is easily seen when the proportions of their fixed elements are compared with those as they exist in the whin-rock of the neighbourhood.

Fixed elements.	Covering of horizontal bed.	North dyke parallel to Hett Dyke.	Interior of horizontal bed.
Silica .....	51.56	52.05	52.05
Alumina .....	20.72	17.88	15.50
Protoxide of iron .....	15.47	12.58	12.90
Lime .....	7.38	9.47	13.83
Magnesia .....	3.33	5.82	4.02
Potash and soda .....	1.54	2.20	1.70
	100.00	100.00	100.00

The chief change, therefore, in composition which the outer portions of the bed of whin have experienced is a much greater absorption of carbonic acid, amounting to nearly nine tenths of the total quantity required for converting the iron, lime, magnesia, and alkalis into carbonates.

It is perhaps a difficult task to speak with any degree of confidence on the precise nature of the causes which have given rise to certain differences in the proportions of some of the earths as exhibited in the above figures. We may, however, readily imagine that a liquefied rock, during its passage through a series of stratified beds of various kinds and of different thickness, will continue for a longer or a shorter time in contact with any given substance, according to the size of the latter, or according to the rate at which the stream of fluid matter for the time being is travelling. It is also equally easy to suppose that the exterior may solidify by contact with cooler surfaces when the basalt has assumed the composition resembling that of the crust or coverings already described. The liquid torrent continues to flow through beds in which lime preponderates, such as the mountain limestone: an additional quantity of this earth is dissolved, and the basalt, thus altered in composition, is expelled through a kind of gigantic tube formed by the cooling of the first portions of the ejected mass.

As a source of silica and alumina I would point to the composition of the rocks immediately below the thin seam of coal underlying the horizontal bed of basalt under consideration.

considered the changes which the intruded igneous rock  
e, the alterations may be examined which the presence of a  
highly heated matter has effected on the adjacent sedimen-

amount of volatile constituents left in the thin seam of  
ly underlying the bed of whin in the pit has been already  
at a distance of about 17 feet below this is a second bed of

seems not impossible but that some of the constituents of these strata, common to all, may owe their origin to the basalt itself, from which they may have been emitted in the form of vapour.

Although silica, alumina, and lime are regarded, and justly so, as being little affected by exposure even to a very intense heat, I am nevertheless disposed to believe that all three are susceptible of being evaporated at temperatures not unfrequently used in the arts. From iron blast-furnaces, and particularly from those in the North of England, a vast quantity of white fume or smoke is emitted, which readily condenses on a cold surface. To one of these furnaces in the county of Durham I attached an air-pump worked by steam, and by its means the whole of this fume from a given volume of gas, as it escaped from the furnace, was condensed in water.

On analysis it was found to be composed of—

Silica.....	14.06
Alumina and some peroxide of iron	25.70
Lime.....	2.30
Magnesia.....	trace
Chlorine.....	.61
Sulphuric acid.....	.64
Oxide of zinc.....	19.99
Carbonates of potash and soda....	29.05
Carbonic acid.....	7.83
	<hr/>
	100.18

Not being prepared to find certain of these bodies carried away in the vaporous form, the idea suggested itself that they might, in the first instance, be deoxidized in the powerfully reducing atmosphere of the hearth of the furnace, and subsequently reoxidized in its upper regions. To satisfy myself on this point, I drew a considerable volume of the gases as they exist in the hottest portion of the reducing zone and passed it through cold mercury. Had any such action as that indicated been effected, I would expect to find potassium or sodium in the mercury. No trace, however, of these metals was detected, and I therefore concluded that the furnace-vapours in question must be regarded as true sublimates. If so, and if the estimate of the quantity be correct, many thousands of tons of alumina &c. are annually evaporated on the banks of the Tees during the process of smelting iron.

If similar vapours were emitted by basalt when intensely heated, it is almost certain that, under the great pressure then prevailing at the depth of this particular bed, some portion would find its way into the adjoining strata. Lying above the basalt is some 8 or 9 feet of a rock spoken of as "white post." On referring to the analysis formerly quoted, it will be seen that this bed contains 88.25 per cent. of silica (it is there-

I. L. Bell on *Changes in Basaltic Veins.* [June 17,

iceous rock), and that its remaining 11.75 parts consist of of which occur in the basalt. It is true the same at the rocks underlying the stratum of whin, and that in both ingredients, found in small quantities, may have been deposited material constituting the main body of the bed.

However, in the possibility of the basalt having been the or a part of what may be designated as foreign ingredients post, three specimens were submitted to examination. One in the bed where it adjoins the whin, a second from its the third from its upper portion; and certainly, so far as ingredients are concerned, they tend to confirm the view. This view is based on the fact that the substances in found in greatest quantity next the basalt, and that they diminish in this respect as the distance from the basalt in-

Although Professor Jukes expresses himself as confident of the origin of this substance, he nowhere had an opportunity of examining it in contact with basalt previous to its alteration. The presence of carbonic acid and water he ascribes to subsequent infiltration.

XV. “Results of Magnetical Observations made in Little Namaqualand during a part of the Months of April and May, 1874.”

By E. J. STONE, M.A., F.R.S. Received June 11, 1875.

An eclipse of the sun was to occur on April 16, 1874, which would be total throughout Little Namaqualand. I made arrangements for a visit to this country to observe the eclipse. The country is one rarely visited. I was not aware that any determinations of the magnetic elements had been made there, except a few of the variation by the Admiralty surveyors at one or two points along the coast. It appeared to me desirable that the opportunity afforded by my visit to observe the eclipse should not be lost of securing magnetical observations at several stations in Namaqualand. An application was made to the Colonial Government for some assistance. An ox-waggon was required for the transit of the magnetical equipment and of a wooden building which had been prepared to protect the instruments and the observers whilst at work. The sum asked for was sixty pounds. The request thus made was, however, refused, although with great courtesy and apparent reluctance, from a supposed difficulty in passing such a grant through Parliament. I was, however, most unwilling to abandon the idea of making these magnetical observations. When the facts of the case became known, I received offers of assistance from some gentlemen in Namaqualand, and His Excellency Sir Henry Barkly, K.C.B. &c., kindly interested himself in the matter and afforded me all the facilities in his power. I determined therefore to carry out, in a somewhat modified form, the scheme of observations which I had arranged. The wooden building was left behind. I found that good observations could be made without cover of

the instruments or the observer, although at a considerable distance from the instruments, and in the comfort of those engaged upon the work. The disturbance arises from the action of the wind upon the instruments, especially upon the dip-instrument; but by patiently awaiting the injurious effects arising from this cause can be very nearly quite eliminated. I decided also, after some hesitation, to have an assistant with me. I was anxious to avoid unnecessary exertion, and to obtain as great freedom for moving about the country as was absolutely required some one to enter the times from a watch to the nearest half-second; and I found, after a careful trial of the instruments upon the point, that my wife could do this without error. The probable error of these time determinations does not exceed three tenths of a second; and it would be very difficult, even with an assistant, to obtain, under the circumstances of these observations, a much greater degree of accuracy. The instrumental equipment consisted of:—a “Dip,” by Dover; a “Unifilar,” variation, and azimuth instrument combined, by Elliott Brothers; a five-inch Theodolite for the determination of the latitudes, local times, and absolute magnetic declination; aneroid barometer; thermometer; and a pocket chronometer beating half-seconds. With only two persons and this equipment, it was found possible to move freely about the country in a horse cart, and with comparative luxury in a waggon.

of the magnet was found as follows :—The passage of the line of reference in the needle over the wire of the observing-telescope was noted at every tenth complete vibration passing right and passing left. If  $t_1, t_2, t_3$ , and  $t_n$  are  $n$  observed times of these passages right, we have for the time of a semivibration

$$r = \frac{3}{10} \frac{1}{n+1} \left\{ \frac{2}{n(n-1)} [0 \times t_1 + 1 \times t_2 + 2 \times t_3 + \dots + (n-1)t_n] - \left[ \frac{t_1 + t_2 + \dots + t_n}{n} \right] \right\},$$

and a similar expression for the time from the passages left.

The probable error of the mean of these two determinations can be shown to be

$$\frac{e}{10} \sqrt{\frac{3}{2} \frac{1}{(n-1)n(n+1)}},$$

where  $e$  is the probable error of a single time determination.

In the Namaqualand observations  $n$  was usually 6. If, therefore,  $e = 0.3$ , we have for the probable error in the times of vibration

$$0.0025.$$

I think this error rather in excess than defect.

The Dip Observations consisted of a bisection of the upper and lower ends of the needle after each lift of the needle; both microscopes were read each time. There were never less than four of these independent lifts in each position; a complete dip therefore consisted of at least sixty-four independent bisections of the ends of the needle and of thirty-two independent lifts of the needle from the agate planes. A great deal of time was consumed in making one of these dips in the open air, on account of the disturbances of the instrument by the wind. In the zenith-distance observations of the sun for local time, and azimuth observations for the determination of the absolute azimuths of the marks, both limbs of the sun in reversed positions of the theodolite were always taken. The differences between the azimuths of these marks, usually two, and the azimuthal reading for the magnetic meridian were taken with the Elliott instrument. The means of the results obtained from the variation-needle, which allows of reversed suspension, were alone used; but the reading for the magnetic axis of the vibration-magnet, which is well adjusted, was usually taken as a check. To save time the deflection observations were only made at the distance of one foot, except for the Port Nolloth station. The small correction to the results thus found, usually determined by a second set of deflections at 1.3 foot, has been obtained from the Port Nolloth observations and other determinations at the observatory. The longitudes of the stations are only very rough approximations. No attempt was made to fix them with any greater accuracy than

for the necessary interpolations of the sun's declination. I am permitted to mention that the observations whose results are contained in the present paper could hardly have been made without the assistance afforded me by E. J. Carson, Esq., and R. T. Hall, Esq., C.E., Engineer, of the Cape Copper Company. Thanks are due to them for a thoughtful kindness which facilitated my work, and yet rendered a working trip into a wild country one of great enjoyment.

## PORT NOLLOREN.

1½ miles far from the Cemetery, Sandy Velt.

11<sup>h</sup> 7<sup>m</sup> 28<sup>s</sup>. South latitude 29° 15' 30".

*Dip Observations.* Needle A, B, Dover.

11, April 10, 11 <sup>h</sup> .	A, South .. . . .	53° 19' 30"
	A, North .. . . .	53 26 3
	Dip .. . . . =	53 22 46

Wind was very high at times during these observations; but the results were satisfactory.

14, April 11, 10<sup>h</sup>. Temperature 61°·2.

Produced by the vibrating-magnet:—

10° 56' 13"

The absolute azimuths of these marks determined on April 10 were as follows:—

Azimuth of northern mark.....	147° 8' 22"
„ southern mark .....	6 4 33
Variation from northern mark .....	28 54 17
„ southern mark .....	28 54 52
Variation, April 12, 10 <sup>h</sup> .....	28 54 35

*Vibration Observations.*

April 12, 11<sup>h</sup> 20<sup>m</sup>. Temperature 72°. 90p = 2' 10".  $\tau_1 = 5^{\circ}0543$ ,  $\tau_2 = 5^{\circ}0529$ ,  $\tau = 5^{\circ}0536$ .

The changes of temperature were considerable; at times a cold damp mist passed over from the sea.

The latitude was determined on April 12, near noon, and found to be 29° 15' 30".

On my return to Port Nolloth I was detained six days waiting for the steamer, which lay outside the bar, but could not cross on account of rough weather. During the greater part of this time a dense damp mist prevailed that rendered observations impossible. I was, however, anxious to repeat, at least, the determination of the variation; and this was done on May 3, 3<sup>h</sup>. The station was one rather nearer the sea than that first chosen.

Temperature 70°·2. 90p = 10' 17". Correction —0' 55".

Azimuthal reading for magnetical meridian, May 3, 3<sup>h</sup>:—

Suspension direct .....	319° 17' 24"
„ reversed .....	318 51 48

Reading .....

Torsion correction .... =

319 3 41

Reading for mark ..... 320 27 2

Excess of reading for mark ..... 1° 23' 21"

The azimuth of the mark was found as follows:—

1874, May 3 ..... 152° 26' 49"

May 5 ..... 152 26 41

The variation on May 3, 3<sup>h</sup> = 28° 56' 36". The results for Port Nolloth are therefore as follows:—

V = Variation = 28° 55' 36" { mean of results for April 12  
and May 3.

X = Horizontal force = 4·4464

m = Magnetic moment = 0·4264

D = Dip = 53° 22' 46"

F = Total force = 7·4540

## [June 17,

pproximate longitude.....  $1^{\text{h}} 10^{\text{m}} 45^{\text{s}}$   
pproximate south latitude .....  $29^{\circ} 14' 15''$

al reading for magnetic meridian.....	91 30 31
al reading for magnetic axis of vibration-	
.....	91 28   0

*Vibrations.*

Three sets were taken; the first two were observed at unequal intervals, and were made somewhat under difficulties. Some ostriches bore down upon the instrument and had to be continually driven from it. The mean of the first two sets, however, agrees very closely with the third.

From the first two sets  $r=5^{\circ}0608$ .

The last set gave:—

1874, April 15, 11<sup>h</sup> 6<sup>m</sup>. Temperature  $80^{\circ}2$ .  $90p=3' 53''$ .  $r_1=5^{\circ}0600$ ,  $r_2=5^{\circ}0603$ , or  $r=5^{\circ}0602$ .

The value  $r=5^{\circ}0606$  has been adopted.

*Deflections.*

April 15, 3<sup>h</sup>. Temperature  $87^{\circ}2$ .

$$\text{Distance 1.0 foot } \left\{ \begin{array}{l} 10^{\circ} 48' 35'' \\ 10^{\circ} 52' 27'' \\ 10^{\circ} 55' 28'' \\ 10^{\circ} 54' 40'' \end{array} \right\} u = 10^{\circ} 52' 48''.$$

Hence for the Klipfontein station we have:—

Variation.....	V=	28° 23' 21"
Horizontal force....	X=	4.4343
Magnetic moment ..	m=	0.4279
Dip .....	D=	53° 21' 56"
Total force .....	F=	7.4312

The total eclipse of the sun was observed from this station on April 16. The sky was perfectly clear from clouds during the whole day.

## OOKIEP STATION.

Approximate longitude ..... 1<sup>h</sup> 11<sup>m</sup> 33<sup>s</sup>

Approximate south latitude..... 29° 36' 15"

This station was 3059 feet above the level of the sea. This height is derived from Mr. Hall's levelling. The instruments were placed as near Mr. Carson's house as would insure freedom from any disturbing effect of the iron about the house. Ookiep is surrounded by mountains, which impeded very early or late observations of the sun from the station chosen. It is the chief mining station, at present, of the Cape Copper-Mining Company.

*Dip Observations.*

1874, April 18, 11 <sup>h</sup> .	A, South .....	53° 9' 58"

#### ORANGE-RIVER STATION.

Approximate longitude ..... 1<sup>h</sup> 12<sup>m</sup> 56<sup>s</sup>

Approximate south latitude .... 28° 53' 7"

The observations were made near New Raman's, Nisbetbath, or Schuyte drift. These three names are given to fix the particular drift to which reference is made. It was a narrow gorge, surrounded by mountains of some considerable height, some rising to 3000 and 4000 feet. The height of the station above the sea appeared, from barometrical determinations, to be about 780 feet. A mountain-pass, of about 750 feet, separated the river from the Bushman flats. These flats, in this neighbourhood,

*Magnetic Observations in Little Namaqualand.* [June 17,

on similar barometrical determinations, to be from 1500 to  
the sea-level. The position was not altogether a favour-  
magnetic observations. I had but little choice of stations.  
the local magnetic disturbances in the observations made  
at the elements might have been found to have differed  
considerably with a comparatively small shift in geographical  
should therefore have been glad to have supplemented these  
with a set on the Bushman flats, the bed of a recent sea  
islands (kopies); but this could not have been done with-  
arrangements for the supply of water.

The numerous observations for time at the different stations have not been given, as of no interest.

I arrived in Namaqualand on April 9, by the Union steamship 'Namaqua,' Captain Barker, reached Port Nolloth, on my return, on the evening of Wednesday, April 29, but did not sail until Wednesday, May 6, reaching the observatory on Saturday, May 9.

XVI. "On the Proportions of the several Lobes of the Cerebrum in Man and in certain of the higher Vertebrata, and on an attempt to explain some of the Asymmetry of the Cerebral Convolutions in Man." By JOHN MARSHALL, F.R.S., F.R.C.S.E., Professor of Surgery, University College, London, &c. Received June 17, 1875.

1. I desire to communicate to the Royal Society the fact that I have, by severing the cerebral hemispheres in certain definite directions in Man, and also in some of the higher Vertebrata, and by then weighing the separated portions, not only arrived at some interesting and important results as to the relative size of those portions in different animals and in Man, but I am enabled to state that this method, applied to the brains of individuals of different race, sex, age, education, and occupation, seems likely to furnish a means of investigating individual peculiarities in the human cerebrum.

I propose shortly to communicate my results to the Society.

2. I have likewise made numerous observations on the convolutions of the human brain with the view of explaining their symmetry in certain regions, and their asymmetry in others. In endeavouring to trace more particularly the causes of the asymmetry of the convolutions which prevails in Man, I have been led to believe that some, at least, of this is due to the right-handedness of Man.

I find, on studying a large number of human cerebra, that there are stronger evidences of *essential* asymmetry, as distinguished from what I would term *non-essential* asymmetry, in the immediate neighbourhood of the left fissure of Rolando, and next to this part in the right parietal lobule.

There are certain secondary essential asymmetrical conditions which may be pointed out, and besides this many non-essential and very variable ones.

*Influence of Stature on Weight of Encephalon.* [June 17,

can be given in support of these propositions from the  
of fetal brains and the brains of idiots, the former of which  
markable, *early*, and special tendency to deviations in sym-  
neighbourhood of the left fissure of Rolando.

is as merely a preliminary notice of a future communication.

the Influence of Stature on the Weight of the Ence-  
and its parts in Man." By JOHN MARSHALL, F.R.S.,  
S.E., Professor of Surgery, University College, London,  
received June 17, 1875.

ous, for a certain special purpose, to determine the influence  
the weight of the encephalon and its parts in Man, I have,  
assent and ready assistance of Dr. Robert Boyd, further  
MS. records of the numerous data accumulated by him,  
e framed his tables published in the Philosophical Trans-  
61.

first, that, as might be expected, an increase of stature is  
by an increase in the absolute weight of the encephalon or  
both sexes.

sexes together, the total increase, with a mean range of

sexual difference in the weight of the male brain overrides the influence of stature, or subsists in spite of his greater stature, which has a tendency to diminish his proportionate amount of brain.

Further comparisons show that the stature ratio, as it may be called, diminishes with the height less markedly and less constantly in the case of the cerebrum than in the case of the cerebellum, which latter organ, therefore, obeys the influence of stature more exactly and implicitly, so far as regards its relative proportion to the body.

3. It becomes evident, and may be shown, that all estimates of other influences regulating the brain-weights in Man, whether these be sex, age, occupation, education, or disease, are liable to error unless the influence of stature be first eliminated. Instances of this statement are easy to find.

4. It may in this mode be demonstrated what is the true influence of sex, age, disease, and other modifying causes.

5. Lastly, in this way alone can we arrive, as it seems to me, at a correct appreciation of that residual cause of peculiarity or deviation in the weight of the encephalon and its parts, especially of the cerebrum, which may be called its *proper weight=variation*, as an independent or quasi-independent organ.

6. This residual variation, it may be thus shown, is far larger than any other, a fact obviously of the highest interest and importance.

In support of these propositions, and others of greater detail, I propose to make a lengthened communication hereafter.

**XVIII. "On a General Method of producing exact Rectilinear Motion by Linkwork."** By A. B. KEMPE, B.A., of the Inner Temple, late Scholar of Trinity College, Cambridge. Communicated by J. J. SYLVESTER, F.R.S. Received June 4, 1875.

Since the invention by James Watt, in 1784, of the 3-bar linkwork known as "Watt's Parallel Motion," which gives an approximate rectilinear motion, many attempts have been made to obtain a more perfect solution of the problem how to obtain accurate rectilinear motion by means of linkwork. Professor Tchebicheff succeeded in obtaining a 3-bar linkwork giving a much closer approximation to a true result; but in his case, as in that of others, the solution is only approximate, and it may be, in fact, shown that with 3 bars an accurate result cannot be obtained. It was not until 1864 that the problem was solved; in that year M. Peaucellier made his memorable discovery of an accurate 7-bar solution; and in 1874, when the subject was brought prominently forward in England by Professor Sylvester, Mr. Hart, in a paper read before the British Association, gave a solution by means of 5 bars. Both these linkworks, as is now well known, depended upon the inversion of a circle with respect to a point on its circumference.

Mr. A. B. Kempe on the production of [June 17,

er's apparatus is shown in fig. 10.  $PO, OK, KD, DP$  bars joined together at their extremities;  $PB, KB$  are equal, but unequal to the four others; they are jointed to  $P$  and  $K$  and to a fixed pivot at  $B$ . It is then easily seen this linkage\* is deformed,  $B, O, D$  remain in a straight line, product  $BO, BD$  is constant. Thus if  $D$  be made, by bar  $AD$  jointed to the fixed point  $A$ , whose distance from  $B$  to describe a circle through  $B$ , the point  $O$  will describe the circle—that is, the straight line  $OL$  perpendicular

apparatus is shown in fig. 15. For the six bars  $BP, BK, K, KO$  of M. Peaucellier in fig. 10 he substitutes the

$$BC=B'C', \quad CD=C'D',$$

the points,  $P, O, V$ , on a line parallel to  $CC'$ ; these points, linkage be deformed, lie in a straight line, and the product  $PO, OV$  is constant.

g made, by the bar  $VU$  equal to  $PU$  and pivoted at  $U$ , to the passing through the fixed point  $P$ , as in the case of this linkwork,  $O$  describes the straight line  $OL$  perpendicular

lecture on M. Peaucellier's discovery delivered by Pro-

The property alluded to is this:—

*The cosines of the opposite angles of any quadrilateral whose sides are of constant length, but whose angles are variable, bear a linear relation to each other.*

§ 1. In fig. 1,  $ABCD$  is any quadrilateral of which the sides  $AB$ ,  $BC$ ,  $CD$ ,  $DA$  are of the lengths  $a$ ,  $b$ ,  $c$ ,  $d$  respectively.

Fig. 1.

Then it is clear that

$$a^2 + b^2 - 2ab \cos B = c^2 + d^2 - 2cd \cos D. \dots\dots\dots (1)$$

That is, there is a linear relation of the most general character between the cosines of the variable angles  $B$  and  $D$ .

Before, however, this property can be taken advantage of something more is required; the angles whose cosines bear a linear relation to each other are the opposite angles of a closed quadrilateral; and for our purpose it is necessary that they should be the angles at the base of an open trilateral—i. e., to employ the language of linkwork, the angles made with a third bar by two bars which are jointed to it. To effect this transformation let the second quadrilateral  $A\beta\gamma\delta$  be constructed equal in every respect to  $ABCD$ , and having its sides  $\delta A$ ,  $\beta A$  collinear with the sides  $BA$ ,  $DA$  of  $ABCD$ , but placed in a reverse position so as to be the image of  $ABCD$ . This new quadrilateral may be termed the “conjugate image” of  $ABCD$ , the whole figure forming what may be termed a “self-conjugate sextilateral.”

Mr. A. B. Kempe on the production of [June 17,

that the angle  $\delta$  is equal to the angle  $D$ ; thus we have the  
of the open trilateral  $CB\delta\gamma$  making angles with  $AB$  whose  
linear relation to each other however the figure be de-

ever, the relation is an angle relation, it is unnecessary that  
image should be equal to the original quadrilateral; for if  
 $B'C'D'$  be constructed similar to  $A\beta\gamma\delta$  the angle  $D'$  is  
to the angle  $\delta$ , and we have the sides  $CB, C'D'$  making  
 $B$  whose cosines bear a linear relation to each other. This  
ults more general; and we are moreover able to make the  
 $B'$ , or the points  $D'$  and  $B$ , coincide if necessary. This  
form of figure, consisting of two quadrilaterals, one of which  
d or reduced positive or negative image of the other, may  
appropriately termed a "self-conjugate sextilateral," the qua-  
ng still called the one the "self-conjugate image" of the

et the linkage in fig. 2 be constructed,

Fig. 2.

and

$$B D' = a - kd.$$

$$\text{Thus } N N' = B D' - B N + D' N' *$$

$$= (a - kd) - \frac{\lambda}{2ab} \{2ab \cos B - 2cd \cos D\},$$

by (1)

$$= (a - kd) - \frac{\lambda}{2ab} \{(a^2 + b^2) - (c^2 + d^2)\}, \dots\dots\dots (2)$$

a constant. On the other hand,  $P N - P' N'$  is in general variable.

The linkage in fig. 2, which will assume innumerable forms by giving different values to  $a, b, c, d$ , and  $k$ , is the fundamental linkage upon which the various linkworks here discussed depend. As the same lettering will be preserved throughout the diagrams, the fundamental linkage may be at once recognised in each figure showing its various adaptations.

For clearness the bars are denoted by thick lines, the joints by round spots; when a bar becomes fixed so that its joints are fixed pivots, the bar is denoted by a broken line and the pivots by circles round the spots. When points in general separate are made coincident, the letters denoting all the coincident points are bracketed together. It is found convenient to collect the different linkworks into four groups, a separate section, numbered to correspond with the figure, being devoted to each separate linkwork described.

I. § 3. Take

$$\lambda = \frac{(a - kd)ab}{(a^2 + b^2) - (c^2 + d^2)}$$

$$\text{so that } N N' = \frac{B D}{2}.$$

Fig. 3.

Then if the bar  $A B$  be fixed and two bars  $P O, P' O$  be added,

$$P O = P B, \quad P' O = P' D;$$

$O$  clearly lies on  $A B$  however the linkwork be deformed, and its locus is therefore the straight line  $A B$ .

\* In the figure  $D' N'$  is negative.

to B A in opposite directions; and the linkwork is one of those given by me in the 'Messenger.'

Fig. 6.

§ 7. This case does not strictly come under the same head as those coming before, but is an exceptional one.

Fig. 7.

Since P and P' in § 5 lie vertically the one over the other, it is clear that if the links  $PO = P'B$ ,  $P'O = PB$  be added, O lies on the straight line OB perpendicular to AB, and thus OB is the locus of O.

II. § 8. Make  $k = \frac{a}{d}$  in the fundamental linkage, so that B and D' coincide.

Fix AB, add the bars RPO, RP'O, making

$$\begin{aligned} RP &= PO = P'D', \\ RP' &= P'O = PB, \end{aligned}$$

Mr. A. B. Kempe on the production of [June 17,

$BP O$  is parallel to  $P' D'$ ,

$BP' O'$  „ „  $P B$ .

$L, O' L'$  be drawn perpendicular to  $A B$ ,

$N L = N' D'$ ,

$N' L' = B N$ .

$BL = B' L' = N N'$ , a constant.

Fig. 8.

Draw  $OL$  perpendicular to  $AB$ .

Fig. 9.

Then  $NL = N'D'$ .

Therefore  $BL = BN + NL = NN'$ , a constant.

Thus the locus of  $O$  is the straight line  $OL$  perpendicular to  $AB$ .

§ 10. Now in the last linkwork make

$$a = d.$$

Then  $B$  coincides with  $D'$ ,

$$D'K = CB,$$

$$PO = OK = KD = DC,$$

and the linkwork becomes that of M. Peaucellier.

Fig. 10.

IV. § 11. Taking the fundamental linkage in its most general form, fix the point  $P$  on a pivot. Now if the bar  $AB$  be made to remain always parallel to the fixed line  $PS$ , since  $NN'$  is constant,  $P'$  will move on the straight line  $P'L$  perpendicular to  $PS$ .

The parallelism of  $AB$  is effected most obviously by adding the bar  $ST$  equal to  $PB$ ,  $PS$  being equal to  $BT$ . Other methods may, however, be employed; for if  $CA$  be joined cutting  $PS$  in  $U$ ,  $U$  is a fixed point; and if  $UV$  be drawn parallel to  $CD$ ,  $UV$  is constant and  $V$  is a fixed point on  $CD$ . So if  $UW$  be drawn parallel to  $CD$ ,  $UW$  is constant and  $W$

Mr. A. B. Kempe on the production of [June 17,

nt on A D. Thus the bar S T may be replaced by either of  
or U W.

Fig. 11.

the case in which the bar S T is employed in the last

$$a=b, c=d, k=\frac{d}{a}, \lambda=b,$$

coincide with A. Then

C, L, P coincide,

§ 13. In the linkwork of § 11 make

$a=a$ ,  $b=-d$ ,  $\lambda=b$ ,  $=k\frac{d}{a}$ , and make  $D'$  and  $T$  coincide. Then

$S$ ,  $L$  coincide,

$C$ ,  $P$  „

$D'$ ,  $T$  „

$C$ ,  $P$   $O$  „

$B'$ ,  $D$ , „

and the bars  $BC$ ,  $D'C$  make equal angles with  $AB$  in opposite directions ;  
and the linkwork is one of those given by me in the 'Messenger.'

Fig. 13.

§ 14. The peculiar form of the fundamental linkwork employed in the last case may easily be seen to be really the same as was used in § 5. From the property of the equal inclination of the bars  $BC$ ,  $D'C$  to  $BA$ , another form of linkwork may be obtained which does not, strictly speaking, come under this group, but is an exceptional one.

Fig. 14.

Mr. A. B. Kempe *on the production of* [June 17,

duced to any point Q and a point M is taken on BC such  
 Y Q. AB is fixed. The equal bars MO, QO are added.  
 ly moves on the straight OL perpendicular to AB, BL  
 o LD'. This linkwork was given by me in the 'Mes-

ne linkwork of § 11 replace the bar ST by the bar UV.

$$a=d, k=\frac{d}{a}=1.$$

Fig. 15.

describes a straight line  $O_1 B$  through  $B$ , the angle  $O_1 B O_1$  being one half of the angle  $O_1 P O_1$ . This greatly adds to the usefulness of the linkworks.

Fig. 16.

It is not suggested that the linkworks here given exhaust 7-bar line linkworks; indeed it is obvious that many of them are susceptible of variations. Enough, however, has been shown to demonstrate the important part which the property of a quadrilateral combined with the principle of the conjugate image stated at the outset plays in the question.

I have strictly confined myself in this paper to the consideration of the rectilinear motion of a point. The principles involved, however, are applicable to many other problems, as, for example, the motion of bars every point in which moves in one of a series of parallel straight lines or in the same straight line. By means of the peculiar form of the fundamental linkage given in figs. 6, 13, 14, valuable results in the reversal or multiplication of angular motion may be obtained, and a linkage of  $2n+2$  bars may be constructed which will divide any angle into  $n$  equal parts. Some of these questions have been treated of by me in my paper in the 'Messenger of Mathematics,' already referred to, which was, however, written before I obtained the general results here given. The extension of these results to other problems is reserved for future investigation.

Messrs. H. E. Roscoe and B. Stewart on

[June 17,

the Heat of Sunshine at London during the twenty-four  
1855 to 1874, as registered by Campbell's Method." By  
Roscoe, F.R.S., and B. Stewart, F.R.S. Received  
1875.

During the above period Mr. J. F. Campbell observed at London  
the heating effect of the sun in the following manner (de-  
scribed in the Report on the Warming and Ventilating of Dwellings,  
presented to the House of Commons, 25th August, 1857,

A spherical cavity was made in a block of wood, and a spherical  
lens was to be placed in this cavity in such a position that while  
its axis coincided with the centre of the cavity its chief focus was at  
the hemispherical concave surface, the exact point being  
determined by the direction in which the rays struck the

Therefore, the sun shone, a portion of the wood would be  
burnt out by his concentrated beams; and inasmuch as the  
sun changes his position not only from hour to hour, but  
day, it follows that different portions of the wood will be  
burnt out not only from one hour to another, but also from one day to

June 1862	29.509	June 1872	19.675
Dec. 1862	26.795	Dec. 1872	18.158
June 1863	30.115	June 1873	29.191
Dec. 1863	28.325	Dec. 1873	34.443
June 1864	19.258	June 1874	29.478
Dec. 1864	25.209		

The first five of these values must be treated by themselves, inasmuch as the lens was a water one. They point to a minimum of solar-heat action in 1856 and 1857; this agrees very well with the minimum of sun-spot action which took place in 1856.

Of the remaining thirty-three values the mean is 30.468.

Now there was a maximum of sun-spot frequency in 1859 and 1870, and a minimum about the end of 1866 or beginning of 1867.

Let us take the values of sun-heat action about these dates, and see if there be any correspondence. We have sun-heat action, mean date

Dec. 1858=43.607

June 1859=51.521

Dec. 1859=43.858

Mean of the above ..... 46.329,

a value which is greater than the average. .

Again we have sun-heat action, mean date

Dec. 1869=34.193

June 1870=31.750

Dec. 1870=37.680

The mean of which is ..... 34.541,

which is also greater than the average, although the difference is not so decided.

Lastly we have sun-heat action, mean date

June 1866=25.790

Dec. 1866=28.790

June 1867=33.245

The mean of which is ..... 29.275,

which is less than the average.

Staff-Commander E. W. Creak on the

[June 17,

as appear that, as far as we can judge from these observations, there is more solar heat at London in years of maximum than in years of minimum disturbance.

very well with a remark made by Messrs. De la Rue, Howard, and Cowey, the Kew Observers, to the effect that the number of solar pictures might be taken in a year on which solar pictures might be taken appears to be greater in years of maximum than in years of minimum activity.

**The Effects of Iron Masts on Compasses placed near**  
By Staff-Commander E. W. CREAK, R.N. Commanded by Captain EVANS, R.N., F.R.S., by permission of the Admiralty Commissioners of the Admiralty. Received June

of the position of the standard compass on board ship, and of the position of the standard compass on board ship, and of the position of the standard compass on board ship, is one of the greatest importance with respect to navigation. In H.M. ships it is one of the principal duties of the commanding officer to secure the best possible position for the standard compass, and when that position has been determined, to ascertain the horizontal and vertical components of the total magnetic force resulting from the iron used in the construction and equipment of every

fects. In these papers may be traced in turn the effects of adding steam-engines and boilers, iron beams, and armour plating; but until lately no good opportunity has occurred for accurately defining the action of iron masts in producing compass disturbance from observation. The case referred to is that of H.M.S. 'Undaunted;' and when about to visit that ship in the ordinary course of my duties in the Compass Department, I was directed by the Hydrographer to make a special series of observations of the horizontal and vertical forces at all three compasses, as the lower masts and bowsprit were of iron.

To prepare the way for a discussion of the results of these observations, it appears necessary to give a short history of the two principal vessels mentioned in this paper, and also to go over some already well-trodden ground, whilst taking account of all the iron and the effects on their compasses, until the question of the iron masts alone remains to be settled.

For some years past there have been lying in Sheerness harbour two wooden frigates of exactly the same build, tonnage, and horse-power, namely, the 'Undaunted' and 'Newcastle'—the only important difference between them being that the 'Undaunted' has iron masts, the 'Newcastle' wooden. The diagonal iron riders which form the principal portion of the iron used in construction of their hulls are about 6 inches in breadth,  $\frac{3}{4}$  of an inch thick, and placed 5 feet apart, at an angle of  $45^\circ$  with the decks. They extend from about 5 feet from the keelson on both sides of the ship up to the top sides—the after riders inclined towards the bow, the foremost towards the stern, the two sets meeting and overlapping amidships. These riders, therefore, being separated are independent magnets, except at the point of meeting just mentioned.

The 'Newcastle' was built at Deptford, head S.  $73^\circ$  W. (magnetic), and is a vessel of 3035 tons and 600 horse-power. The 'Undaunted' was built at Chatham, head S.  $43^\circ$  E. (magnetic), and is a vessel of 3039 tons and 600 horse-power. Assuming the dip at the time of building to be  $68^\circ$ , the after riders of both ships (near which the compasses are placed) were not far removed from the direction of the Earth's Total Force, and would therefore become strongly magnetized, especially those in the 'Undaunted.'

A glance at the coefficient C of the standard compasses given in the Table shows at once which ship was built in the easterly and which in the westerly direction; and, further, it is highly probable that in the 'Newcastle' the coefficient B would have been more nearly in accordance with the results of direction of the ship in building, but for the masses of iron introduced in equipment, such as engines and boilers, armament, great funnel, &c. In fact, as the compass is only 62 feet from the stern, there is a large excess of iron before that position compared with that abaft. We may reasonably assume the same of the B in the 'Undaunted' before her iron masts were stepped.

time to say something about these iron masts. The bow-mast are so far removed from the compasses that their influence is regarded as zero. The mainmast also being at a distance from the standard compass, its red and blue poles must be regarded as another. At the steering-compasses a slight repulsion may exist, but sufficiently small to be neglected.

However, we consider the position of the mizzenmast, at a distance of 8 feet 6 inches from all compasses, we shall find that it produces deviations of very decided amount and marked character; our attention may be confined to that mast alone.

The mizzenmast, which is 82 feet in length and 24 inches in diameter, is made of the "best-best" iron, half an inch thick, the thickness being making it 1 inch thick at its thickest parts, and for the purpose of this discussion may be considered a hollow cylinder. The influence of iron in that form have been already treated on mathematically by Mr. Archibald Smith, F.R.S., in the *Phil. Trans. Roy. Soc.* vol. 18, pp. 317, 318.

When the mast lay in a horizontal position, the direction was S. 43° E., heel towards the northward, which was a position for that end of the mast to receive a permanent magnetism as the riveting was proceeding. When the mast was placed in its nearly vertical position and subjected to the

\* The position of this compass is in the centre line of the ship and the same height above deck as the steering-compasses; both of the latter may therefore be compared with it.

Staff-Commander E. W. Creak on the

[June 17,

was built at Woolwich, head S.  $16^{\circ}$  W., and fitted out at the coefficients obtained in her at two positions have been confirm and supplement those of the 'Newcastle,' especially of the same construction, although smaller, and has

and methods of computation of these coefficients are the Admiralty Manual of the Deviations of the Compass. and compasses are all within 3 inches of 12 feet 6 inches over deck, the steering-compasses 3 feet 9 inches above that apart.

tion of the values given in the Table shows that about  $8^{\circ}$  led to the B of the 'Undaunted's' standard, but the C really unaltered. This is evidently the effect of the red st repelling the red pole of the compass towards the bow, piring with the other iron of the ship to produce a large e mast and compass being in the same fore-and-aft line, be altered, and depends for its amount and sign on the s before referred to. There is nothing unusual in the D, E, except that the 'Undaunted's' D ranks among the d in wooden vessels.

the ratio of the mean horizontal force on board to that on d to all the compasses a fraction above unity. This

C, D, E of the steering-compasses to be considered. For this purpose there is sufficient evidence in the two sister ships, which are strictly comparable.

The compasses are necessarily placed out of the central line of the ships, and diagonally to the mast under discussion; therefore, as shown by the figures in the Table, a transverse component is introduced. In effect the iron mast has increased the B of the 'Undaunted's' steering-compasses by about  $16^{\circ}$ . To the +C of her starboard steering-compass about  $11^{\circ}$  have been added, and at the port steering a large -C of  $13\frac{1}{2}^{\circ}$  shows the transverse component of the mast's force more strongly than at the starboard; but the  $2\frac{1}{2}^{\circ}$  in excess are probably due to some other cause not accounted for by the observations made.

The A for these compasses is large in both ships; this does not, however, appear to proceed from magnetic causes, but rather from mechanical error in placing the binacles. D and E show the results usual in wooden ships, except the D in the 'Undaunted,' which is slightly increased.

Having thus, I think, defined the effects of the iron mizzenmast of the 'Undaunted' on her compasses, it remains now to show what was the most desirable way of meeting them, and what was actually done in that direction.

The most certain cure of the evil would have been to remove all the compasses further away from the mast, as far as magnetic reasons are concerned; but this would have entailed serious alterations in the arrangements of the ship which the occasion by no means warranted.

The standard compass might have been raised to a level with the neutral zone of the mast, but this at the expense of increasing vibration in the card from greater length of pedestal.

The steering-compasses being in the most suitable position for the use of the helmsman, and there being the standard compass as a means of comparison and obtaining the correct course, no change of position was necessary. The three compasses were therefore corrected by magnets, the semicircular deviation being reduced to the same amount as in the 'Newcastle.' It was not thought desirable to correct the whole of the semicircular deviation, as the mast, when the ship should make large changes of latitude, would probably add to the changing part of that deviation observed in this class of ships.

#### *Conclusions.*

The effects of iron masts are these:—

1. They produce semicircular deviation, and the objectionable addition to that deviation known as heeling-error.

2. That these effects need not always be avoided, as in certain cases they may be made useful in experienced hands: for example, the principal mast in this discussion (as shown in the accompanying sketch, p. 588) might, in an iron ship built head north, be used to correct the -B of

the standard compass, and oppose the downward pull of the ship's vertical force.

3. That the quadrantal deviation is slightly increased, and the mean directive force remains undisturbed.

4. Lastly, it is suggested that, as the magnetic condition of a mast may be easily ascertained by carrying a compass round it at stated distances and parts, the mast may be utilized or avoided as convenient. A similar examination of the mast in different latitudes would enable an observer to eliminate the effects of transient induced magnetism from the subpermanent. The amount of deviation proceeding from these causes is known for several classes of ships; but what part iron masts supply is yet a subject for inquiry.

END OF THE TWENTY-THIRD VOLUME.

## OBITUARY NOTICES OF FELLOWS DECEASED.

HUGO VON MOHL, born April 8, 1805, was the fourth of five brothers, all of whom were men of note, either for public services or intellectual ability. His father was some time Minister at Wurtemberg for Home Affairs and Worship, while his mother, a person of exceptional gifts, was the daughter of Autenrieth, Finance Minister in the same State.

Von Mohl's early education was obtained at the Gymnasium of his native town, Stuttgart. In his nineteenth year (1823) he entered the University of Tübingen, where (in 1828) he graduated in medicine. In his inaugural dissertation (alluded to below) he clearly foreshadowed the course in science in which he was to preeminently excel. It was his father's wish that he should devote himself to surgery. This, however, was distasteful to him; and the intercourse into which he was thrown during the next few years with Von Martius, Zuccarini, Steinheil, and other botanists, soon determined the direction of his pursuits. In 1831 he contributed to the great work of Martius on Palms a memoir on the structure of the stems of those plants. In this year he was nominated first "adjunct" to the Botanic Garden of St. Petersburg, a post which, however, he did not accept, owing to his being appointed Professor of Physiology at Bern, whither he went in 1832. After the death of Schübler he returned, in 1835, to Tübingen as Professor of Botany in the University; and here he remained, notwithstanding many brilliant proposals tempting him elsewhere, till the time of his death. The interests of the University of Tübingen were matters about which he felt a keen solicitude, and the foundation of a Faculty of Natural Science in that University was essentially his work. In 1843 the Order of the Crown of Wurtemberg was conferred on him and he was ennobled. About this time he was obliged to make a prolonged stay in South Tyrol on account of delicate health. He recovered; but although a man of great stature and robust build, he appears, after he had accomplished his sixtieth year, to have fallen into chronic ill health. He suffered from pleurisy and attacks of diarrhoea. Eventually he became very reserved in manner and subject to giddiness. On the morning of Easter Monday, April 1, 1872, having been cheerful and well the night before, he was found dead in bed.

These particulars are derived from the memoir which appeared in the 'Botanische Zeitung' for 1872. Von Mohl was elected a Foreign Member of the Royal Society, March 26, 1868.

In describing fully Von Mohl's scientific career and position, it would be necessary to write the history of vegetable histology. His work is practically coincident with the application of the higher powers of the microscope to the investigation of vegetable tissue. Confining himself almost exclusively to the higher classes of plants, from the group of Muscineae upwards (and neglecting the Algae, Fungi, and Lichens), there is hardly a point of any consequence in which some research or investigation

is not the solid foundation of our present knowledge. The Scientific Papers of the Royal Society enumerates 78 of not including various dissertations, some of which, along with the more important of his papers, were in 1845 collected and in a quarto volume, under the title of "Vermischte Schriften." His publications which accompanies the memoir in the *Zeitung* gives the titles of no less than 90. Nor were his the only way in which he contributed to the advancement of the minute anatomy of plants. In 1843 he commenced, in conjunction with Schlechtendal, the '*Botanische Zeitung*,' a small weekly periodical of eight pages, occasionally illustrated with which he continued to edit till the time of his death. The journal chronicle, year by year, the gradual development of the microscopic study of plants, a field in which (doubtless in no small measure to the example of Von Mohl) German science has reaped a most abundant harvest than that of other nations. No one can fail to appreciate the thorough character of Von Mohl's scientific work. His papers are always ready to turn themselves to any part of his subject which seemed to need investigation, or the results of others to their examination or criticism. His papers are, in their way, contributions to knowledge." Except when they are controversial, they commence with a careful history and estimate of the work

In 1832 he also described the movements due to irritability in various species of *Robinia*. In a paper on Lenticels he disproved the theory of De Candolle that these structures were in any way dependent on the production of adventitious roots. His memoir on the stems of *Cycads* appeared also this year.

In 1833 he worked out the anomalous structure of the stomata in the *Proteaceæ*, which Robert Brown had regarded as imperforate and had described simply as "glandulæ cutanæ." He contributed to the 'Icones Plantarum Cryptogamicarum Brasilæ' of Von Martius a description of the anatomy of the stem of tree ferns. Hitherto the course of their vascular bundles had been supposed to be very similar to that of *Monocotyledons*. Von Mohl was the first to explain the structure of the hollow fenestrated cylinder into which the bundles are combined, and subsequent observers have added little to his account. In a memoir published in the 'Flora' he described the development of the spores in various of the higher *Cryptogams*. He gave the first accurate account of the development of the moss-capsule, pointed out the development of the spores in fours in one mother-cell, explained the development of the elaters of *Jungermannia*, and gave a correct account of those of *Equisetum*.

In 1834 he published an elaborate paper on pollen, in which he detailed an immense number of observations. It is true he fell into error in regarding the external coat as in some cases itself cellular. On the other hand, he was able to correct Robert Brown, who, in describing the peculiar movements (which have been called after him) in the granules of the fovilla of pollen, attributed to the granules at the same time a change of form. Von Mohl also established the development of the pollen-grains in fours within each mother-cell, thus indicating an analogy with the development of spores in *Cryptogams*.

The publication by Von Mohl in 1835 of his discovery of the multiplication of cells by division ('Ueber die Vermehrung der Pflanzenzellen durch Theilung') in *Cladophora glomerata* has been the starting-point of all subsequent investigations into the development of the tissues and organs of plants. It revealed, in fact, the precise mode by which vegetative growth is accomplished. Mirbel, in his memoir on the development of *Marchantia*, communicated to the Académie des Sciences in 1831 and 1832, but not published till 1836, had described the formation of pollen-grains by the quadripartite division of a mother-cell. This, however, though an extremely important observation, is not a case of growth, properly speaking, and does not affect Mohl's historical position in the matter. In 1838 Schleiden announced the multiplication of cells by the formation of new cells in their interior as a general law in the vegetable kingdom. He was supported by Nägeli. The views of Von Mohl, developed as they were by Meyen and Unger, eventually established themselves. In a paper on the structure of cork and bark, Von Mohl described the nature of the tissues which enter into their composition, and accounted for the

their character in different plants, especially the enfoliation  
 mark in such trees as the Plane.

In the year (1836) Von Mohl developed his theory of an inter-  
 space in which the cells of tissues were held to be imbedded.  
 This cement is now known to belong to the cell-walls them-  
 selves, and not to be a substance independent of them. Mohl indeed,  
 practically withdrew his views upon the matter ('Die vege-  
 tation,' 1850). He also, in 1836, gave an account of the singular  
 fungus (*Testudinaria*) *elephantipes*.

Von Mohl published the results of his investigations with  
 chlorophyl. They still remain essentially undisturbed. He  
 showed that chlorophyl-granules were soft and homogeneous bodies, and  
 not, as had been supposed; he detected in them the presence  
 of starch. Having asserted that chlorophyl-granules possess a  
 fibrous structure, Von Mohl returned to the subject in 1855, and  
 showed that his view was untenable. During 1837 he also published a  
 paper on the structure of vegetable membrane, in which he declared  
 that "cell-membranes to possess a fibrous structure." The objec-  
 tion raised by Von Mohl is one of very general truth, although a  
 different set of considerations are now brought to its explana-  
 tion. The paper on the porous cells of *Sphagnum* finally put to rest the  
 question as to their nature. He contributed an examination of some

final account of the matter. In the same year he published his investigations on the cuticle of plants, which he demonstrated to be organically derived from the epidermic cells. He further supported this view in papers published in 1847 and 1849.

Von Mohl's researches in 1843 ('Ueber den Milchsafte und seine Bewegung') demolished Schultz's analogy of latex to blood. They were published in the 'Botanische Zeitung,' which was started in this year.

In 1844 Von Mohl maintained, against the theory of Dupetit-Thouars, the dependence of the growth of Dicotyledons on the physiological activity of leaves. The same year he published his remarks on the structure of the vegetable cell, which for a long time immensely influenced the course of vegetable histology. He regarded the cell-wall as generally composed of a primary external imperforate membrane, and a secondary one usually perforated with apertures. This he supposed to be lined by a third membrane, "Primordialschlauch," the primordial utricle of English writers. "This membrane forms a perfectly closed, cell-like, thin-walled vesicle, which in the fresh plant is closely applied to the inner wall of the cell, and therefore escapes observation; while in specimens which have been preserved in spirit it is contracted, and more or less detached from the wall of the cell."

In 1845 Von Mohl published a memoir on the Flora of Wurtemberg. It is interesting to find a great physiological botanist engaged in work of this kind, which it is rather the fashion at present to depreciate. Von Mohl enters at some length into the causes which influence the local distribution of plants; and it is in regard to points of this kind that he attaches scientific importance to local floras. An examination of a monstrous state of *Poa alpina* led him to the now generally received opinion that the lower floral glume of grasses is not a perigonial leaf but a bract. To the same year belongs a paper on the penetration of cuticle into stomata.

Von Mohl's paper, "Ueber die Saftbewegungen im Inneren der Zellen," published in 1846 (Bot. Zeit. p. 73), has been the starting-point of all modern views about the vegetable cell. He first described accurately the "opaque viscid fluid of a white colour, having granules intermingled with it, which fluid I call *protoplasm*." He observed the vacuolization of the protoplasm until it forms a mere network. He described the motion which takes place in the filament of the network, "or perhaps now first becomes visible," and he measured its rate. Schleiden gave the theory its finishing touch in the third edition of his 'Principles' (1849), by identifying Mohl's primordial utricle and circulating fluid.

In 1847 Von Mohl confirmed the researches of Amici (for whom he had a high regard) on the impregnation of Orchideæ, which, in his judgment, made an end of Schleiden's theory as to the origin of the embryo in Phanerogams, although the controversy was carried on for some time longer by Hofmeister, Tulasne, Schacht, and Radlkofer. He also published an elaborate memoir, which has been translated into both French

researches on the structure of "liber" brought out some facts. He had already been the first (in 1836) to examine care. He pointed out that bast-cells were far from being constituent of the liber as had been supposed, and that they accompanied, or even entirely replaced, by the "Gitterzellen."

on Mohl discovered the extremely curious fact that the known as "gum tragacanth" is produced by the alteration of the pith and medullary rays of various species of

Square, Edinburgh, on the 11th of November, 1793. His mother's maiden name was Jane Edmond. It appears, from a memorandum in Dr. Grant's handwriting, that he was sent from home to be nursed, and saw little of either of his parents during his infancy and childhood. He had eight brothers and three sisters, all of whom died before him; and as none of them left any children, Dr. Grant was the last survivor of his family.

When about ten years old he was placed at the High School of Edinburgh, where he continued for five years, under the tuition, successively, of Mr. Christison (afterwards Professor in the University), Dr. Carson, and Dr. Adam, the Rector, author of the well-known work on Roman Antiquities. In 1808 his father died; and in November of that year Dr. Grant became a student in the University of Edinburgh, attending the junior classes of Latin and Greek. In the following November he entered on his curriculum of medical study, and during its course attended the several classes in the Faculty of Medicine under the Professors of that day. He also studied Natural History under Professor Jameson, and attended the lectures of some of the extra-academical teachers. After completing his course of medical study, he in 1814 took his Degree of Doctor of Medicine, and published his inaugural dissertation, "*De Sanguinis Circuitu*."

In the mean time he had obtained (in May 1814) the Diploma of the College of Surgeons. In November of the same year he was elected one of the Presidents of the Medical Society of Edinburgh, a place justly regarded as an honourable object of ambition among the young aspirants in the Medical School.

Rather more than a year after taking his degree Dr. Grant went to the Continent, where he spent upwards of four years. During this time he visited various places of interest in France, Italy, and Germany, and made a pedestrian tour in Hungary; but his principal stay was in Paris, Rome, Leipsic, Dresden, Vienna, and Munich, on account, no doubt, of the varied opportunities for scientific study and general culture afforded by these foreign seats of science, art, and learning. He returned to Edinburgh in the summer of 1820, and took up his residence in his native city. At a later time he became a Fellow of the Edinburgh College of Physicians; but he seems not to have engaged in medical practice—his career had taken another direction. He had early imbibed a taste for Comparative Anatomy and Zoology, and now devoted himself assiduously to the prosecution of those branches of science, both by continued systematic study and by original research. The study of the invertebrate animals was peculiarly attractive; and at this time Dr. Grant published various interesting anatomical and physiological observations on mollusks and zoophytes; and his name will always be associated with the advances of our knowledge concerning the structure and economy of sponges, to the investigation of which Dr. Grant at this time enthusiastically applied himself. The pools left by the retiring tide on the shores of the Firth of

and favourable opportunities for observation ; and he would patiently watching the phenomena exhibited by these humble their native element.

remained in Edinburgh till 1827, and in the mean time communicated the results of his various scientific inquiries to the ' Edinburgh Journal ' and the ' Memoirs of the Wernerian Society,' of which he became an active member. He was also (in 1824) elected a member of the Royal Society of Edinburgh.

In 1827 Dr. Grant was elected Professor of Comparative Anatomy in the newly founded University of London, afterwards University College. He was not altogether new to the work of teaching. He had already, though brief, experience in Edinburgh, in 1824, when he, who for some years had delivered lectures on Comparative Anatomy during the Summer Session, entrusted him with the part of the course related to the anatomy of invertebrated animals. He entered London in 1828, and in October of that year delivered his inaugural lecture, which was published at the time and went through two editions. In this office he continued up to the time of his death, during the period of forty-six academical years he never omitted a single lecture, which was a point on which he justly prided himself. Up to the last year (1874) he continued to give five lectures a week ; but, sensible of the length, he proposed to reduce the number to three in the next

gical Society. In 1837 he was appointed Fullerian Professor of Physiology in the Royal Institution, which office he held for the usual period of three years. At a later time he was appointed by the Trustees of the British Museum to the Swiney Lectureship on Geology, the tenure of which is limited to five years. In 1841 he delivered the Annual Oration before the British Medical Association. In 1836 he was elected a Fellow of the Royal Society of London. He was also a Fellow of the Linnean, Zoological, and Geological Societies.

Dr. Grant's vacations were spent sometimes in Scotland, but chiefly abroad, in France, Germany, Belgium, and Holland. On more than one of these occasions he was accompanied by an intelligent and favourite Hindoo pupil, Dr. Chuckerbutty, who afterwards became a Professor in the Government Medical College of Calcutta. Dr. Grant seems to have had a special liking to Holland, which he visited and revisited several times—partly, no doubt, on account of its scientific institutions and zoological museums, but largely also for the sake of acquiring the Dutch language. In like manner he afterwards spent his vacation in Copenhagen, and worked hard at Danish. Indeed it is to be noted that he had a great taste for the study of languages, both practical and philological, and spoke the principal European tongues fluently.

Dr. Grant's lectures were reported in the early Numbers of the 'Lancet' (1833-34), and he afterwards published a treatise on Comparative Anatomy which embodied the substance of them. The work came out in parts, but was not completed. He was also author of the article "Animal Kingdom" in Todd's 'Cyclopædia of Anatomy.' The titles and dates of his communications to periodical works are given in the Royal Society's 'Catalogue of Scientific Papers.' They are 35 in number, and extend from 1825 to 1839.

Dr. Grant was a devoted lover of music, and attendance at operas and concerts was one of his chief enjoyments in his latter years.

In August 1874 Dr. Grant suffered from a dysenteric attack, for which at first he would have no medical advice; and although subsequently, by appropriate treatment, the virulence of the disease was subdued, his strength was exhausted, and he died on the 23rd of that month at his house close by Euston Square. He was buried in Highgate Cemetery, attended to the grave by a few old friends and attached pupils, among whom was his friend and former companion in travel, Dr. Chuckerbutty, who was then in England, and two months later was destined to follow his venerated master.

Dr. Grant was never married. He knew of no surviving relatives. Three of his brothers, whose deaths he has recorded, were military officers. Of these, James, a lieutenant in the German Legion, fell at the siege of Badajoz in 1811; Alexander, captain in the Madras Engineers, died in the Burmese war in 1825; and Francis, captain in the Madras Army, as already mentioned, died at Edinburgh in 1852.

By his will Dr. Grant bequeathed the whole of his property, including

s and library, to University College, in the service of which the greater part of his life, and to the principles of which he was deeply attached.

ENNIS, C.E., past President of the Institution of Civil Engineers, born August 30, 1794. He first assisted his father, the late Sir John Ennis, in building both Southwark and Waterloo bridges. After his father in 1821 he succeeded him as Engineer to the Corporation of London Bridge (for which he received the honour of knighthood), the completion of Ramsgate Harbour and Breakwater (commenced by his father), the Earl of Lonsdale's Harbours at Whitehaven, a portion of those at Cardiff, and the carrying out of years of the great system of drainage and land reclamation in Lincolnshire fens, also works at Newry and Dundalk. He was engaged in a noble work on Harbours, of which Her Majesty was pleased to accept the dedication, and for which he received honours from their Imperial Majesties the Emperors of Russia and Austria, also of a monograph on Plymouth Breakwater, and a small treatise on Engineering in the form of a Presidential Address to the Institution of Civil Engineers. In conjunction with his late brother, Sir John Ennis, he contributed to introduce the screw-propeller into the navy.

LAMBERT ADOLPHE JACQUES QUETELET was born at Ghent on the 22nd of February, 1796. He had the misfortune of losing his father at the early age of seven; and the poverty of his family obliged him to seek his own livelihood at once on leaving the Lycée. He obtained an appointment as teacher of mathematics, drawing, grammar, &c. in a school at Oudenarde. At the end of a year he returned to Ghent; and in February 1815, the very day on which he completed his nineteenth year, he was appointed to the Chair of Mathematics at the New College, which had replaced the Lycée. This appointment was not a brilliant one; but with the private lessons which he had the opportunity of giving, it afforded him a subsistence, and he had the satisfaction of feeling himself independent. He had even some leisure to devote to science, his flute, drawing, and to literary composition. About this time he, in conjunction with his intimate friend and former schoolfellow Dandelin, wrote an opera, entitled "Jean Second ou Charles Quint dans les murs de Gand," which was favourably spoken of. Dandelin soon afterwards left Ghent; and Garnier, who had become Professor of Mathematics at the University of Ghent, persuaded Quetelet to return to science. He studied the higher mathematics under Garnier, and at the same time assisted the latter by giving some of his lectures.

In 1819 he took the degree of Doctor of Science, the first conferred in that University. On this occasion he gave a brilliant inaugural address, in which he made known his discovery of a new curve of the third degree.

This discovery of the "focale" was much noticed in the '*Annales Beligues*' and in the '*Mercure Belge*,' and was spoken of by Garnier and Raoul as a great honour to the newly founded university.

At the beginning of August, M. Falck, Minister of Public Instruction, came to Ghent, and was present at the laying of the first stone of the New University Buildings. Quetelet was on this occasion presented to M. Falck, and the strong recommendation of him by two such men as Garnier and Raoul led to his appointment shortly afterwards to a Professorship of Elementary Mathematics at the Athenæum of Brussels.

This appointment was made in the beginning of October; and by a private arrangement Quetelet engaged to give one quarter of his salary to his aged predecessor, M. Delhaye, as a retiring pension.

In Brussels Quetelet soon became intimate with the French refugees, David, Arnault, &c., besides frequenting the society of artists and literary men, and the theatres, where Talma, Mademoiselle Mars, &c. gave a series of performances each year.

At this period he composed various verses, and published, in the '*Annales Beligues*,' in the year 1825, an "Essai sur la Romance."

On the 24th of February Quetelet was made a Member of the Royal Belgian Academy of Science, receiving the diploma from Van Hulthem.

The first memoir he presented to the Academy, after his reception,

th of October, 1820, and was entitled "Mémoire sur une méthode générale pour déterminer la surface d'un polygone formé sur des arcs de grands ou de petits cercles, disposés entre eux d'une manière quelconque."

Among are the titles of other papers, also read in the Academy, in November 1820 and February 1826:—

"Conchoïdes Circulaires." Note to "Mémoire sur les Caus-  
tiques soit par Réflexion, soit par Réfraction." "Résumé  
de la Théorie des Caustiques, suivi de différentes applications  
à des projections stéréographiques." "Démonstration et déve-  
loppement de la théorie des Caustiques secondaires."

These researches, already noticed by Gergonne and other distin-  
guished geometers, were particularly remarked on by Chasles, after  
the *Revue de la Correspondance Mathématique et Physique* had given them greater

notice. The memoirs by Quetelet, inserted in the collection of the  
Académie, still remain to be noticed—the "Mémoire sur quelques con-  
jectures géométriques des orbites planétaires" and the "Mémoire sur  
la Géométrie à trois dimensions."

The *Revue de la Correspondance Mathématique et Physique*, already mentioned,  
was published by Garnier and Quetelet early in the year 1825. Its

audiences of all classes of society. He had a true gift for exposition, and could with very simple apparatus make himself clearly understood. In fact he objected to complicated instruments, and said of them that they often serve only to distract the attention from the results which it is the object of the lesson to explain.

Quetelet composed several elementary works for his public courses of instruction. The first in date, "On Elementary Astronomy," appeared in 1826 at Paris, in the 'Bibliothèque Industrielle de Malher,' and was frequently reprinted in France and Belgium, and translated into several languages. In 1827 he published a much more complete work, his 'Astronomie Populaire.' This latter was shortly followed by 'Les Positions de Physique,' which is considered superior to the 'Astronomie.' He endeavoured subsequently, in a little volume entitled "De la Chaleur," to put into practice his idea of founding instruction in Elementary Physics on experiments within reach of all. His intention was to follow this up by similar treatises on Magnetism, Electricity, and Light. Quetelet wrote the chapter on Acoustics in the 'Physique,' contributed by M. Plateau to the 'Encyclopédie Populaire.' Finally, he published in 1828 'Instructions Populaires sur le Calcul des Probabilités,' which was a *résumé* of the lessons he had been giving for several years at Brussels.

His public courses of lectures had been more and more successful ever since 1824. The government now deemed it advisable to organize other lectures of the same kind; and towards the end of 1826 the Administrator General Van Ewyck requested of Quetelet, on the king's behalf, a report on the matter, and on the 17th December the Museum of Science and Literature was established by a royal decree at Brussels. Quetelet was chosen for the Chair of Physics and Astronomy; but as he already gave courses of lectures on these subjects in his capacity of Professor at the Athenæum, he obtained leave to give a course on the History of Science at the Museum. He did not, however, long continue to give this course, as he left the Athenæum at the beginning of the year 1828, when he transferred his courses of Physics and Astronomy, which he had been giving at the latter institution, to the programme of the Museum, and these he continued to give until the close of the session 1833 and 1834.

The usefulness of the Museum was much diminished by the Revolution of 1830; and after languishing for a few years that institution was finally absorbed in 1834 by the Free University. A proposal was made to Quetelet to join the Free University; but this he declined, stating that he considered such an appointment to be inconsistent with his duties at the Observatory, to which he had been appointed on condition of not taking any other. He proposed, however, to continue his courses at the Observatory, those of Physics and Meteorology during the winter, and that of Astronomy during the summer evenings. This proposal was not acceded to; and Quetelet for a short time gave up public teaching, in

already been engaged for twenty years. He, however, on it again, for, by a royal decree, Jan. 6, 1836, he was professor of Astronomy and Geodesy at the École Militaire. Here he paid much attention to falling stars, and gave a method of determining the height of aerolites, by making simultaneous observations from different points. He also made experiments on the magnetic inclination of the needle.

He held very earnest views on the subject of education, and he endeavored to make them publicly known—once under the Government of the Low Countries, once after the Revolution of 1830.

On a commission instituted by King William in 1828, he was one of the minority who wished to emancipate public instruction. He advocated the reduction of the number of Universities, and the establishment of Polytechnic Schools—one for the northern provinces of the Netherlands, and another for the southern provinces. Finally, he maintained that it had come for substituting the use of modern languages for Latin, still in use.

In 1823 and 1832 Quetelet was much occupied with Statistics; and his publications on this subject have perhaps contributed more than others to popularize his name.

A memoir was read to the Academy, and entitled "Mémoire sur les naissances et de la mortalité à Bruxelles."

Quetelet had been deputed by Government to attend the Meeting of the British Association for the Advancement of Science which was to be held at Cambridge, beginning on the 25th of June, 1833. He went by Paris, where he read at the Institute his memoir on Mortality.

At Cambridge he took a warm interest in the establishment of the Statistical Section, of which Malthus, Babbage, and other *savants* became members.

In London he was summoned before an Inquiry Commission instituted by Parliament, to furnish information on the mode of keeping the Civil Registers of Belgium, and on the Census of the 1st of January, 1830.

Quetelet was one of the most active members of the Academy of Sciences at Brussels, and was always very desirous of promoting its independence. In 1834 he was appointed Permanent Secretary.

In 1835 he brought out an '*Annuaire de l'Académie*.' About this time also he wrote for the British Association a paper of great interest, entitled "*Aperçu de l'état actuel des Sciences Mathématiques chez les Belges*."

Quetelet was appointed by the House of Representatives one of the Central Jury of Science. He retained these functions for some time, and showed great kindness and sagacity in discharging them.

In the course of the year 1835 there appeared at Paris the chief of all Quetelet's works, "*Sur l'homme et le développement de ses facultés, ou Essai de Physique Sociale*." It was a *résumé* of all his previous works on Statistics.

In February 1836 Quetelet was charged with the execution of a Royal Decree for the establishment of a little meridian in the cities of Antwerp, Ostend, Bruges, Ghent, and Liège, and for placing a meridian-instrument on the walls of the Cathedrals, Hôtels de Ville, or other suitable buildings of forty-one different towns.

In August 1839 Quetelet made a journey, in company with his wife, in France, Italy, and Tyrol. His object was threefold. In the first place, he was to compare, in conjunction with his fellow commissioners, Messrs. Dumortier and Teichman, the standard weights and measures of Belgium with those of France; secondly, he was to attend the Congress of Savants at Pisa; and thirdly, he purposed to revise the determinations of magnetic intensity obtained in 1830, of the correctness of which he entertained some doubts.

At the sitting of the 7th December the Academy received a report of the proceedings of the Commission in the month of August; and Quetelet also presented the results of the Magnetic Observations which he had made in Tyrol and Italy.

In 1839 Quetelet communicated to the Academy a new Catalogue of the most remarkable appearances of falling stars—the second which he had made, for he had early turned his attention to this subject. *Es*

ver, to have been in some uncertainty as to the nature of  
ena.

1839 was marked at the Observatory by the commencement  
ions on the flowering of plants, and in the month of January  
first of a series of monthly magnetic observations. These  
ns were made at the suggestion of the Royal Society of  
as in the year 1839 that Quetelet was elected a Foreign  
e Royal Society; and in May 1841 these observations were  
extended, and were thenceforth made regularly day and night  
two hours.

1841 was an important period of Quetelet's life. He  
he time was past for individuals to promote the advance-  
ce by their isolated efforts, and that further investigations  
be conducted by people associated together in academic  
42 he drew up a set of instructions as to the choice of  
he reports. These instructions embraced Meteorology and  
raphy and the Animal Kingdom.

etelet published "Lettres à S.A.R. le duc regnant de Saxe  
théorie des probabilités appliquées aux Sciences Morales et  
hich was reviewed by Sir John Herschel in the 'Edinburgh  
n afterwards he published a work entitled "Du Système  
les qui le régissent."

accounts were first inserted in the '*Mémoires*' of the Academy, and those on the atmospheric waves, which had appeared successively in the '*Annales*' of the Observatory, were afterwards united with other works on meteorology, and published under the title "*Sur le Climat de la Belgique*."

Quetelet married in 1825 a daughter of M. Curtet, a French physician, and niece of the well-known chemist Professor van Mons, a highly accomplished lady, by whom he had a son and a daughter. He was very hospitable, and entertained at his house persons of distinction who came to Brussels—artists, savants, literary men, and politicians of all parties.

In July 1855 he was seized with a fit of apoplexy, which was pronounced by the physicians to be serious. His memory was much injured by it, although after a week or ten days he wished to resume work; and in the September following he was able to be present at the public Meeting of the Section of Fine Arts.

He continued to work during the remaining years of his life; and, in fact, when misfortune came heavily upon him by the loss of his wife, his daughter, and several of his grandchildren, work became his only consolation.

His son, M. Ernest Quetelet, had now taken the direction of the Observatory, and Quetelet occupied himself with Meteorology, Physical Geography, and Statistics. He continued to preside at the Central Commission and assisted punctually at the International Congresses of Statistics, which were held in the great capitals of Europe. Six months before his death he made the fatiguing journey to St. Petersburg in consequence of a pressing invitation from the Grand Duke Constantine, under whose auspices the Statistical Congress was to be held. Neither the fear of cholera nor the anxious entreaties of his family could deter him from this enterprise. On his return he seemed refreshed, having been pleased by his reception. About this time also he had been made an Associate of the Academy of Moral and Political Science of the Institute of France; and ten days afterwards, in a congratulatory address sent to the Royal Academy of Belgium on the occasion of the hundredth anniversary of its foundation, the Academy of Sciences at Berlin proclaimed him the founder of a new science.

To the last he was punctual in fulfilling his duties as Perpetual Secretary of the Academy. On Monday, February 2, 1874, although already suffering from the attack of bronchitis which carried him off a fortnight later, he was present at the Literary Section. On the Thursday he went for the last time down to his study, and was with difficulty prevented from going to the Meeting of the Fine-Art Section. He became rapidly worse, and expired on the 17th of February.
